Pull the main circuit breaker that feed your house with AC.
Set your radio up to work on a battery.
This will help you determine if problem is in your house or outside.

Hello All,

I just started to heat up the iron on the Ugly Weekender. In building the VFO section I find in the Schematic that L1 has a tap. In reading through the article I only find that L1 calls for 25 Turns no. 22 on T50-6, no mention of a tap. Does anyone have this info? Thanks for any help

I have had something like this. It was worse around 7 MHz.

It was from a neibourg's touch lamp. I could even toggle it's lamp on and
off by transmitting a carrier on 7 MHz.

ARRL has info on this on their server.

You too? It certainly gets really busy, especially when you're trying
to get other stuff done, like senior project and trying to stay active
in the hobby! I have learned alot though, in the past couple of weeks,
not so much from school but from working on my senior project--an 80m CW
transciever. Building it, having the tools to debug it (all the test
equipment in the lab, etc), having had some classes on theory, and last
but not least, having wise knowledgable profs around to help with
questions has taught me more about electronics than the year or two of
circuit theory!

Good luck on the finals!

Good news indeed.

Interestingly, I built a version of the 20m Universal transmitter from this book using a rather unusual construction technique:

http://ourworld.compuserve.com/homepages/Al_Williams/foil.htm

You can find a picture at the URL. I won't give too much away except to say: shoe boxes and stained glass....

5401. Ferrite vs iron powder

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-05 00:00:00 UTC
From: Shawn Upton <supton@eece.maine.edu>
Message-ID: <3669CEDC.2D85@eece.maine.edu>
Source record: 76125

I'm interested what the differences are between these types of
torriods. I am building a design that used both, but I had only access
to the iron type. I looked up the Al values, and found not much
difference between the two. So, I subsituted, and it worked ok. But,
for future knowledge, just what makes one better than the other?
Thanks.

I've received many good suggestions so far, and I appreciate the response. A lot of other folks seem to have a similar problem as well.

I have not "thrown the main breaker" yet, simply because I don't like the idea of having to go around and reset all the clocks, VCR's and anything else that blinks for my attention after an extended power outage. But, let me tell you what I found out last night.

I started suspecting the circuit that all of the radios were on because when my scanner was operating on the AC adapter, the interference was much stronger than on battery power. It dawned on me that I still had my Yaesu KSC-14 Rapid charger plugged in. I unplugged that device and the level of the interference dropped significanly, on the order of 2 S-units on 10 meters and even more further down the spectrum.

Now I must listen very closely to find it, but it is still there.

My next step is to determine if the interference is still originating within the house or not. At this point, it is no longer stong enough to create a problem. I just have to remember to unplug the Rapid Charger when I'm not using it.

It has become a quest to locate the source of the problem though, so more to follow....

I have some modern Electronics Fundamental Text books available. All are currently in use at various colleges. They are all Associate Degree (Technician) level. All books are NEW.

Basic Electronics by Grob - 8th edition - 1997 - $ 30

Electronic Principles by Malvino - 6th edition - 1999 - $ 30

Electric Circuit Fundamentals and Electronics Fundamentals - 3rd edition by Floyd - 1995 - $ 30

Electronic Devices and Circuits by Hassul and Zimmerman -
Conventional Flow version - includes student workbook
I think this is a 1998 copyright, but it is still in shrink-wrap, and I do not want to unwrap it to find out for sure. $ 30

Prices do not include shipping from Florida. By the way, most of these are big, heavy books, weighing about 6 pounds each.

E-mail to W8EK@usa.net

For other ham items for sale, see http://www.gnv.fdt.net/~kenmar

Thanks.

I assume there's no black band or similar marking on one end of the
case. I have some 10uF, 50 volt plastic (not electrolytic) capacitors.
They're about 1.2" long and 0.55" diameter. Electrolytics of this
value, even non-polarized, are much smaller. So if it's around this
size, it might be a plastic-dielectric capacitor; otherwise, it's
probably a non-polarized electrolytic. You mention crimping at the
ends. If the case is metal, electrolytic seems more likely. But the
one type of non-polarized electrolytics I have are marked "NP", and I
don't see that marking on yours.

They are "Bi-polar" caps.
k6sde@my-dejanews.com wrote in message <749qr3$34c$1@nnrp1.dejanews.com>...
I bought at a surplus store a few what I thought were ELECTROLYTICS and which were mixed in with other electrolytics. The lighting is never very good in those metal warehouse type buildings and I read the value but didn't pay other attention to them. However when I went to solder them into a boat anchor radio to replace an old paper electrolytic I couldn't find a polarity on them

No problem, I thought, I'll put them on my Heath capacitor checker, see which polarity gives the right value and if that doesn't do it, I'll see which direction appears to be shorted or leaky.

The darned things seem to check the same in EITHER direction and the radio works fine with it soldered in randomly. Of course the radio worked fine with the old electrolytic which was so leaky that I couldn't get a measurement of it.

The package is axial and the end caps on them are both insulating, black and both end disks have a small depressed circle next to the lead so the ends are identical. The case is an "electric" blue and the case crimping appears to be identical on either end.

The capacitors have on them a stylized sloping IC with a circled R as a superscript at the end. They are 50V, 10 Mfd units. The other lettering on the case is: BPAM above (J)85 (deg)C and below that 18.

Can anybody identify these? Unpolarized high capacitance caps??? I've never encountered them before.

It was suggested that my capacitor is a non-polarized electrolytic
manufactured by Illinois Capacitor.

I DID find the capacitor on their Web Site. I never would have guessed that
I would be buying a non-polarized capacitor for the 15 or 20 cents apiece
that I paid for them. They DO seem to work fine in place of the "antique"
electrolytic that was in the circuit before.

THANKS FOR THE HELP!

Ian, K6SDE

>
> Artur
> 12.4.98

(Excuse me if any of these sound blatantly obvious :)

1. Have you driven it into compression to get +25dBm out? If so,
then the transistor may be going partially into cut-off &
dropping the average Icc (class A2). Removing the signal lets it
be at its actual quiesent point (230mA). To verify, drive it &
scope the output, or use a spectrum analyzer to see excessive
even harmonics.

2. Check for oscillation at output - maybe your input termination
upset your tuning vs. your signal generator lead (maybe your
signal generator Zo isn't *exactly* 50 ohms at your test
frequency, or at least not equal to that termination).

2a. Also check that termination! Someone may have overloaded it
& shifted it off value (I used to work for a company that makes
them - they use a wimpy chip resistor).

3. Shorted input cap? but that should DECREASE Icc... Is the base
biasing circuitry stable? Check for noise there...

4. Check input grounding - maybe ground plane is discontinuous.

5. Are you using chip components? If not, maybe you're seeing the
results of parasitics.

From your description of the logo, they were probably
manufactured by Illinois Capacitor, Inc. in Lincolnwood, IL.

You can check out Illinois Capacitor's web pages at:

http://www.illinoiscapacitor.com

Their capacitor specs are published online.

Hello !

This notice is to let everyone on this NG know about
a new ham QRP homebrew site on the world wide web.
The address is

http://qrp.pops.net/qrp/default.htm

This site is called the QRP HomeBuilder Webpage and features
information on topics such as receivers, RF amplifiers and diplexers,
transformers and mixers.

Three complete "popcorn" receivers are presented and have
full schematics and construction notes.

The web page is on our family server near Seattle, WA and it should
hold out against heavy internet traffic.

thank you

Jenna Tashley

If you can't figure it out, get yourself a JPS ANC-4. It'll do a job on the noise. I have one and it amazes me how well it gets rid of local noise. It connects between the antenna and the radio and with its own - seperate antenna - picks up mostly the noise and lets you cancel it out using some phase adjustment on the ANC-4.

I had that problem several years ago. In my case it turned out to be
the touch-controlled table lamps that I bought at Sams. They have a
nasty oscillator cirtuit (rich in harmonics) that gets back into the
house wiring and radiates from there. Grounding the brass lamp stand
cured the problem, but the touch-on feature quit working. With my rig
in my car, I could hear it all the way out to the drop from the pole.
Good luck!

The main site for Ham Radio information for Winnipeg and the province of Manitoba is:

http://www.winnipeg.freenet.mb.ca/amradio/

It is hosted by a "FreeNet" provider and the service can be pretty slow - so be patient. It also hasn't been updated since the spring of this year - they're still promoting last spring's fleamarket! You will find links to all of the repeater, packet and club sites in the region there, though.

For a more up-to-date listing of area Ham activities, check out the Ham Radio homepage for Winnipeg's neighbour city, Selkirk at:

http://www.sirnet.mb.ca/~ve4sss/

There are about a dozen repeaters in Winnipeg, however the most popular are on 146.610(-600), 147.390(+600) and 145.350(-600).

There is a 2-meter net on Sunday afternoon, and one night during the week (Thursday, maybe?). All the regional links are brought up, and you can talk across most of the province, and into N.W. Ontario.

You've picked the strangest year in memory to visit "Winter-peg" Not a spot of snow on the ground, and temperatures hovering around the freezing point. They're usually 2-feet under and 15 degrees below zero (Celsius) by now. If you have any winter activities planned, pray for a blizzard...soon! :)

The newsgroup for the region is:
news:man.ham-radio
Good luck finding any messages there. BTW - What does this have to do with homebrew amateur radio? ;)

5423. Re: Ferrite vs iron powder

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <3669EA2A.572DD1B4@teleport.com>
Source record: 76134

Powdered iron cores are made from, well, powdered iron, in a clay-like binder, compressed. Ferrites are made from a combination of metal oxides, then fired to become a ceramic.

In general, powdered iron cores have lower relative permeability than ferrites (although they do overlap some, as you noted). One of the attractive features of powdered irons is that they can take much higher flux density than ferrites before saturating, so they're widely used as inductors in switching power supplies.

There are about three types of material commonly used by amateurs: Low-frequency, high-permeability ferrites (e.g. 70-series and type 43 material), high-frequency, low-permeability ferrites (e.g., 60-series material), and low-permeability powdered irons (e.g., type 2 and 6 materials). The type numbers I'm using are the ones used by Amidon (Fair-Rite ferrites and Micrometals powdered irons).

Among these, the powdered irons will produce the highest Q inductors through the HF range at least, with the lowest temperature coefficient. They're used for inductors in transmitter output matching networks, antenna tuners, filters, and tuned circuits. The low-frequency ferrites are very useful as cores for broadband transformers at HF, because their impedance is quite high. It's also resistive, and stays fairly constant over a very wide frequency range, so you don't see big resonant effects. The high-frequency ferrites perform this role at the high end of the HF spectrum and into VHF. Low-frequency ferrites are also useful for EMI suppression because of their resistive nature at HF and above, and are widely used for this purpose.

In addition, I've used low-frequency powdered iron cores for RF chokes at HF with good results. They become lossy like ferrites when used at these frequencies, and they'll take quite a lot of DC current without saturating.

The AL value is frequently misleading, and often useless. It's o.k. if you're using the core in a frequency range where its Q is reasonably high (below 100 kHz or so for 70-series ferrites, a few hundred kHz at most for type 43, and a few MHz for 60-series; or anywhere in the HF or VHF range for type 2 and 6 powdered iron). But low-frequency ferrites are extremely useful at much higher frequencies. At these frequencies, their impedance is primarily resistive, and the AL value doesn't apply. To find out the impedance per turn squared, you need to either measure it or get the data from the manufacturer. (Most now characterize many of their low-frequency ferrites at higher frequencies.)

This has necessarily been very brief. There are whole books written about the topic (and most aren't very accurate), but it's a complex subject. I've found that many engineers, even ones actively designing RF circuitry, don't have a very good understanding of it. So you aren't alone!

5430. audio transformers for homebrew regen. sets - w.t.b.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: Ron Ostman <w0nyq@minntaccdp.com>
Message-ID: <74eci9boa1@news.ispn.net>
Source record: 76141

Wanted - audio transformers for homebrew regenerative receiver projects.
Misc. impedance ratios - 3 to 1, 5 to 1, whatever you may have. Let me know
and I'll decide if it fits the bill.

Thanks,

Ron Ostman, W0NYQ
Mt. Iron, MN

5431. I.F. and BFO coils - 455/1600 kc - w.t.b.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC

Message-ID: <74ecnlboh1@news.ispn.net>
Source record: 76142

Looking for i.f. transformers and bfo transformers for homwbrew superhet. projects - preferably slug-tuned types of the larger style (not the new 3/4" cans).

Thanks,

Ron Ostman, W0NYQ
Mt. Iron, MN

5432. Wanted: Help with RFI problems on 42-50 Mhz

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: onealcom1@aol.com
Message-ID: <19981206135242.12527.00000799@ng136.aol.com>
Source record: 76143

I have a 1988 Lincoln and the digital display for the clock and verious other functions causes my lowband maxtrac mobile to have a constant RFI noise on 46 Mhz. I can shut power down to this unit to relieve the noise, but I lose with it all of my engine warnings such as engine temp and oil pressure. It is all combined in one unit. I also have problems on several other vehicles but know of no cure. Anyone who may be able to help, I would sure appreciate suggestions. Thanks!

Dave

Ron!!!!

Just what I need!! I'll take it if still available.
E-Mail me your phone # and a good time to call and I'll
ring you up and lets make a deal.

Thank you!!

5436. Forsale, prototyping PCBs

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: ed ngai <engai@sprintmail.com>
Message-ID: <366AE7CC.653CB6FF@sprintmail.com>
Source record: 76147

Sorry for the 'Forsale Post', but I think that this will really help
you develop your electronic/HAM projects.

I've designed some prototype boards and they've come in handy for
me the last few years. What I've done is made some PCBs w/ the layout
pattern for typical connectors placed on the edge of the PCB. So now
if you want to make a prototype and you have to add a connector,
DB-25, DB-15, DB-9, 40 pin header (like an IDE connector), 96 pin DIN
connector, all you have to do is get the connector and solder it down.
You don't have to spend alot of time drilling out a huge hole for the
connectors. This saves about 1 hr., to up to 1/2 day just in adding
some
connectors.

I can mail you drawings of the connectors, if you give me your mailing
address.

Cost : $18.00 for each prototype PCB. expensive, but compared to
some other off the shelf prototype PCB, I know these are better.
They save me time in adding a connector to get my projects connected
to other equipment.

The PCBs are 0.062" thick, but I can make them around 0.040" or 0.030"
to make them lighter, flexible. Or I can make them thicker for a
strong base.

Here's the description,

Debug-010 PCB : actual size 6.75 " x 6 " x 0.062" thick
via grid pattern 0.100" , circular pads 0.075", holes 0.030"
power traces top and bottom,
Connector layout patterns on the edges of the PCB are
(4) DB-25, (4) 40 pin header, (1) disk drive pwr. connector.

Debug-020 PCB : same dimensions as Debug-010, but w/ diff connectors.
Connector layout patterns on the edges of the PCB are
(2) DB-25, (2) DB-14, (1) DB-9, (2) 96 pin DIN, (1) disk drive pwr.
connector.

Debug-030 PCB :
Connector layout patterns on the edges of the PCB are
(2) DB-25, (2) DB-15, (1) DB-9 (4) DB-37 , (1) disk drive pwr.
connector.

Debug-040 PCB:
Connector layout patterns on the edges of the PCB are
(4) DB-25, (4) DB-15, (3) DB-9, (1) disk drive pwr. connector.

I'm working on another Debug card, same size but w/ a 72 pin SIMM connector. So if you want to add some heavy duty memory to your robot brain this will make it easy. The SIMM connector I'm layout the pattern is for an AMP 821947-7.

Again, sorry for the 'Forsale post'. But I really think these will save you alot of time in building and debuging.

thanks
Ed

5437. TUBES F.S...

Newsgroup: rec.radio.amateur.homebrew

Hi! I do have the tubes listed below for sale:

4x 4-400A(pull from working equip.) $40.00 each
1x 280(pull) $25.00
2x 232(pull) $8.00 each
1x 33(pull) $3.00
1x UX-112(pull) $20.00
1x UX226(pull) $20.00
2x 6550ST(pull) $40.00/pair
2x UX171A(pull) $20.00 each
3x 8791(pull) $100.00 each
2x 6550(few hours used,1ST & 1GT) $50.00/pair
2x 5881 N.I.B. $40.00/pair
2x 5881(used few hours only) $25.00/pair
1x 2050A(new,Phillips,usa) $10.00
2x 2050A(pull) $5.00/each
2x 8417 N.I.B $50.00/pair
1x 931A N.I.B RCA $20.00
3x 7360 N.I.B. GE usa $30.00 each
3x 6267 N.I.B GE $18.00 each
2x 6267(pull) $8.00 each
1x KT66 GEC n.i.b. $70.00
1x 272A Western Elect. NEW $60.00

All pulled tubes are from working equipment,unless mentionned
as new(NIB),if you are interested in some of them,
please email me for more informations.Amounts in U.S. funds.
Thank
S.Caron Revelstoke, B.C.

> They're nothing but a source of endless frustration.

Well, I used to prototype/repair $6,000 and up, bridge/routers , all
SMD
conponents. Solder paste is ok, but try to teach a new hire or
someone who
claims to be an electronic tech. how to use, apply, solder paste and
it's
really frustrating. Not to mention the lost of solder paste if they
leave
it out on the bench overnite. Which as you mention, Solder Balls
Galore !
And how much did that jar of solder paste cost !?

> Proper SMT rework is an art that must be mastered.

Ahh ... yes. Wasn't it Guilliani Marconi that said 'Soldering is an
art'.
As he proceded to light up a big torch to solder some parts together,
circa mid 1800's ? Can you imagine the size of that torch ?

The very first thing I do w/ a PCB is clean it with isoproply alcohol,
IPA.
Even if it comes from the PCB mfg., dosen't matter, clean it w/ an
acid brush,
till it's over clean. Human oils are so easy to get all over the
place.

If your Not using Solder Paste, then 2nd on your list should be flux.
The flux
should be applied w/ a small bottle w/ a needle applicator w/ a 0.010"

hole.
Marshall carries these small bottles. Oh yeah, get only the ESD Safe
bottles,
Kepp all hot plastics away from the workstation 1 meter. And waht
about that
Air Ionizer ? Yes, get Simco, Ion Systems .. what ever, but get an air
ionizer,
don't even think about doing SMD work w/o neutralizing the air around
the work
bench. Unless you like to solder on zap'd parts.

Solder on the size of 0.015" or 0.010" is the only size you should be
using for
SOIC.

> If you are blowing parts around and blistering boards, you don't have your

> when you apply heat, the part will self-align on the pads due to surface
> tension. You should never have to hold a part in place manually. If you
> find that you do, you're doing something wrong.

I remember putting in a request for a Hakko Hot air station for about
$3500,
including all 13 different hot air nozzle tips. Engr. Director
flipout.
Why do much ?! Because each hot air nozzle is for each differnt SMD
IC pattern.
How ever, I've been able to remove some IC's w/ just the 1/8" single
nozzle.
Speed in applying the hot air and care.

And clean the IC w/ IPA and an acid brush. It's so easy to get solder
balls
under SOIC parts and never see them. Douse the PCB, if possible get a
SS tank
and slosh the PCB in the IPA. You'd be surprised to see what comes
out of the
bottom of the tank some times.

> The solder paste that you use has to be fresh. This stuff doesn't have

> wooden toothpick to apply the paste, and use just the tiniest amount
> on each pad. The most common mistake with paste is using too much.

I've gotten these syringe needles from the chem lab and filled them w/
solder
paste. This works well for an applicator, for me. The needel hole is
0.015"
I think? I also use this type of needle to apply heatsink compound
to IC's
transistors, etc. I can get a part number if anyone is interested.
Typically it's a 10cc or 20cc syringe.

> Set your part roughly in place with fine tweezers, and *let go*.

Be nice if you use ESD safe tewwzers. The black ESD safe tip tweezers
are
fileable. What I do is get a small 6" or 8" mill file and file the
inside
faces fo the tewwzers to get therm really facing flat. Ceramic tips
are
also very good. Stainless steel I thought was ok. But I was wrong.
For
an ESD experiment, I wore latex gloves and rolled the SS tweezers in
my
fingers. I then touched the tweezers to a 10 GHz DSO, (LeCroy) and
boy did
I ever see an ESD event. Was impressive when the DSO triggered!
Tried this
w/ a ESD safe glove and still I got a dangerous level of a ESD spike.

I expimented w/ papermate pens and this was bad news. The plastic
barrel was
a great ESD generator and the inside metal ink barrel was equally
opposite on
the trielectric chart. The spark was very high. I'm pretty sure
you'd kill
CMOS parts w/ a ink pen. So I taped the plastic pen barrel w/
aluminum tape
and the ESD spike went away, well diminished about 1/3 to 1/4
intensity.
So now I don't have to buy ESD safe pens.

> Now apply static hot air. When you see the part pull into alignment, remove
> the static hot air source. Let cool. Done. If you are working on a very
> densely packed board, you may want to apply a bit of modeling clay
> over adjacent parts to avoid unsoldering them with the hot air source.
> The clay will peel off easily when you are done and can be reused.
> Keep it in an air tight container when not in use.

Solder paste comes in a jar, so fill your applicator and tighten up
the jar.
If you have a mfg. near you, you can possibly send back some paste to
them
to get re-milled, ie. they take the solids count, add the missing
solvent
and put the paste on a 4 barrel mill. The paste is passed a few times

the
the particle size is measured and sized back to use.

> A good jeweler's loupe and a strong light are essential to SMT work.

I always use a zoom scope, Bausch and Lomb 1:7 Zoom scope .. $850.
Then I get a special telescopeing microscope stand. The zoom scope
can move
up and down 15", but because of the telescope arm, can extend to about
36 "
outward. So now I can work on boards that are 13" or bigger, ie. VME
motherboards are big. And some times I just can't get a mom-brd out,
it's
a panic ship condition, so roll it in, work it, and ship it. Hey I'm
good,
but not everyone can do this. You got to have steady hands.

Jewlers loupes are ok, mine have the old glass type lens, don't know
why today
they sell plstic lens? Bad for the eyes and lousy optics,
aberations. But, I
really don't like getting my face too close to the work. The zoom
scope gets in
close to see alot. I hate missing an IC SOIC leg, where the solder
flows around
the legs but don't solder to the leg ! Like the IC leg was insulated
w/ a clear
plastic. Zoom scope picks it up fast.

> A pair of shot bags on which to rest your wrists are also very handy.

Cool! I used a pair of old jean jack sleeves and filled them w/ sand.
Works
the same way. I wonder why no one sells small bags for rework. Are
we always
to figure out these as we go along?

> This makes your hands *much* steadier, and allows you to do very
> fine work. You don't need a mechanical stage or a microscope. While
> those things are nice in a production environment, in a repair environment
> it takes longer to strip the unit so you can mount it on the stage than it
> would take to just go ahead and repair it in situ with handheld tooling.

I don't use a micrscope stage for rework. My bench top is all wood,
made from
a 8ft. x 2 ft 3/4" plywood. I do all soldering on the wood surface.
Every
few months I put on a coat of ESD floor wax. To re-apply, I just sand
buff it
w/ 200 grit sandpaper and a palm sander. Microscope stages are
Aluminum
anodized and as such can develop horendous ESD charges. Anodizing is

a very
resistive coating, dosn't disgarge ESD fast enough. You have to
remove the
anodizing to do ESD safe SMD re-work.

At work I got the cool ESD safe rubber soldering mat, the dark blue
kind that
wont melt if you slip w/ the soldering iron.

> I pride myself on the fact that you can't tell which component I replaced
> when the job is done. It all looks like factory work. You can do that every
> time once you master the proper techniques. I much prefer working with
> SMT than working with thru-hole leaded parts, or shudder, with point to
> point wiring.

I like that too. It feels good when someone comes by, sees all the
boards
and says when did these come in from the board shop? And I reply they
didn't
I just built them. Looks snazzy huh?

I buy it in the grocery store. Sheets of 33x40 cm (abt 12x15 inches)
for $2 /sheet are sold as reusable baking foil to be used in oven,
grill and microwave. For baking reusable up to 1000x without
butter.The box says it is teflon. Name is NoStik. This is in the
Netherlands, guess there is something like that in the US.

Try this URL: http://www.fix.net/norcal.html

That's the site of the Northern California QRP Club, AKA NorCal. They resurrected the Tuna Tin 2 and associated rigs recently, and have several articles about them on their web page. On the opening page there are three different links titled "NorCal's BACK TO THE FUTURE PROJECT!" These are for the updated Tuna Tin 2 transmitter, CB Slider VFO and Herring Aid 5 receiver. The articles also appeared in QRPp, the quarterly journal of the NorCal QRP Club. (Despite having a name which indicates a regional club, the group actually has quite a large following, with well over 1000 current subscribers to their journal, in just about every state and many foreign countries.)

5446. US Surplus List Update ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: ed ngai <engai@sprintmail.com>
Message-ID: <366B2B61.96C65FE1@sprintmail.com>
Source record: 76157

Hi eveyone, I've been loooking for the US Surplus List. If anyone is interested here's my last info list. Can anyone bonify if these places
exist anymore. If they do, do you have anymore updated info ? I just tried www.paranoia.com and this site ia about to shut down.

Southern Californai Swapmeets, as of 8-91 ,

1st Saturday each month
EL Cajon ARC Swapmeet
Starts 6:15AM
Santee Drive In Theater on Woodside Ave. Hy 67 Santee, Ca

2nd Saturday each month
General Dynamics HRC Swapmeet
Starts 7 AM
GD Valley systems division on the corner of 6th and Cleveland Ave
just East of Haven Ave. north of I-10 at Rancho Cucamonga, Ca.

Last Saturday each month
TRW ARC Swapmeet
Starts 7 AM
on the corner of Marine ave. (Compton Blvd)
and Aviation Blvd. Manhatten Beach, Ca.

Finding the TRW swap meet shouldn't be hard at all. Take the 101 freeway
South ,to the San Diego going south on it until you get to the Rosecrans
west exit. 2 or 3 blocks west will be Aviation BLVD turn left and about
another 2 or 3 blocks on your right will be the swap meet. You can't miss
it. Monitor 146.520 MHz. There is always much activity on that frequency.

Greetings. Here's the most recent surplus list. A couple of notes:

a) The e-mail->WWW service is down ... and not expected to work
anytime
soon. Something about one machine trying to serve the world! It
will
be missed!
b) There still are a large number of states without mention:
Alabama,Alaska,

Arizona,Arkansas,Conneticut,Deleware,DistrictofColumbia(DC),Florida,
Hawaii,Idaho,Indiana,Iowa,Kansas,Kentucky,Louisiana,Maine,Maryland,

Mississippi,Montana,Nebraska,Nevada,NorthCarolina,NorthDakota,Oklahoma,

Pennsylvania,RhodeIsland,SouthCarolina,SouthDakota,Texas,Utah,Vermont,
Virginia,WestVirginia,Wisconsin,Wyoming... Anyone?
c) On the bright side, a number of states have something now, Thanks!
d) Temporarily, you can get the most up-to-date list of this and UK
and
CANADA lists from the TEMPORARY WWW server at URL:

http://alpha.smi.med.pitt.edu:9000/TEMP

It WILL go away when I'm ready to upload my official server with
next upgrade. My official server is at URL:

http://www.paranoia.com/~filipg

e) This list is getting long... ~45KB printed/39KB HTML source. I
might
have to break up these postings into 2 parts... OR compress them
with
ZIP or GZIP and uuencode. I'm NOT volunteering to send them by
e-mail
this time.... uh oh... I made that mistake once too many times ;-)

Here's the list!

Take care.

ANY GOOD SURPLUS PLACES IN USA, <BLAH> V1.25

Notes:
* States that end with a '?' have no entries!
* States that end with a '!' have LOTS of entries!
* We want you to help us transform the '?'s into '!'s ! :-)

Areas in this version:

* California!
* ---Redondo Beach
* ---Sunnyvale
* ---Los Angeles

* ---Rancho Cucamonga
* ---Manhattan Beach
* ---Los Angeles - Swap Meet Schedule
* ---San Jose
* ---San Fernando Valley
* ---Santa Clara
* ---Redwood City
* ---Mountain View
* ---Somewhere/City Unknown
* Colorado
* ---Boulder
* ---Colorado Springs
* ---Denver
* Georgia
* ---Atlanta
* Idaho
* ---Boise
* Illinois
* ---Skokie
* Iowa
* ---Cedar Rapids
* Massachusetts!

Lawrence, Southeast corner, about
1000 feet east on/near Central, enter on funny cloverleaf. Lots of
components (resistors, caps, semiconductors, wire, and such) and
some
computer stuff (vintage)

---SAN FERNANDO VALLEY

(From Robert F. Antoniewicz)

The grandaddy of all such places is a place called APEX in the
north
San Fernando Valley (Just off Lankershim, on S.F. Mission?)

They have more old gear (working and not) than you can glance at in
an
afternoon.

---SANTA CLARA

(From C Martin)

Active Electronics
Somewhere on El Camino Real - Santa Clara
(not surplus and overpriced, but sometimes worth going to).

(From Bob Smith)

Anchor Electronics
2040 Walsh Ave
Santa Clara, CA
Tel: 727-3693

---REDWOOD CITY

(From Dave Turner)

HdB Electronics
2860 Spring Street
Redwood City, CA 94063
Tel: (415) 368-1388

---MOUNTAIN VIEW

(From Dave Turner)

Haltek Electronics
1062 Linda Vista Avenue
Mountain View, CA 94043
Tel: (415) 969-0510
Fax: (415) 964-6973

---SOMEWHERE/CITY UNKNOWN

(From Mark Robert Thorson)

Triangle Machinery, near 880 and 101. A little electronics, but lots
of other interesting stuff (mostly machinery). Lots of air cylinders.
Great prices.

COLORADO

s)
50 New Salem Street
Wakefield, MA 01880

Tel: 617-246-6767

Seem to specialize in computer related junk like old hard drives, etc.

MICHIGAN

---BENTON HARBOR

(From Earl Morse)

Surplus Trading Co
2700 N M-63
Benton Harbor, MI 49022
Tel: 616-849-1800

Lots of surplus from Heath Company and Zenith Data Systems.
Computers
and electronics parts.

Pat Walsh
Located just off of Main street in Benton Harbor, MI

Only open Saturday mornings. Good deals on old Heath and ZDS stuff.
(He gets what Surplus Trading doesn't)

MINNESOTA

---ST. PAUL

(From Brian Schousek)

Well as an electronics surplus store, the Axman is tolerable. I
don't
miss a chance to stop by whenever I'm through the cities. And as
far
as other neat surplus stuff and pure ambience, it can't be beat.
The
original store is at 1639 University Ave. in St. Paul (Just head
east
from campus...watch on your left for a Burger King.) (612)
646-8653.
There are also at least two satellite stores.

(From Steve Jacobson)

Asset Recovery Corp
1907 Charles Ave
St. Paul
PH: 641-0789

Supposed to be pretty good, but not open on weekends. I have never
been there myself.

---EDEN PRAIRIE

(From Steve Jacobson)

All phone # are area code 612

Dexis Corp
9749 Hamilton Rd
Eden Prairie
PH: 944-7670

This place has quite a bit of stuff in a big warehouse.

OREGON

---ALOHA

(From Mark G. Forbes)

Wacky Willy's
Westside Store
2900 SW 219th Ave
Aloha, OR 97006
Tel: (503) 642-5111

AND

Wacky Willy's
Eastside Store
417 E 11th St
Portland, OR 97214
Tel: (503) 234-6864
Fax: (503) 234 2226

Open: Monday-Saturday 9AM-6:30PM

WW has been around since 1980, and they have a diverse collection of
stuff. It seems to come and go pretty fast, so you can't count on
something being there long term. It's not electronic surplus, really,
although you'll find some there. They're more of an industrial/retail
boneyard, where overstocks and errors-of-judgement go to die. A good
place to go if you're looking for stuff to adapt; you might find a
kid's toy for ten cents that you can gut for the case and an LED.

---BEAVERTON (AND SALEM AND EUGENE)

(From Mark G. Forbes)

Norvac Electronics
7940 SW Nimbus Ave
Beaverton, OR 97005
Tel: (503) 644-1025
Tel: (800) 766-1025

They're NOT surplus, just a good source of parts. There's some stuff
there that's used or manufacturer's overstocks, but in general it's
new parts for sale. They're probably the best available source if you
need something specific. They also have stores in Salem and Eugene.

---CORVALLIS

(From Mark G. Forbes)

Zero-Gee Electronics
1890 SW 3rd Street
Corvallis, OR 97333
Tel: (503) 754-9422

Zero-Gee started out as a used bookstore (science fiction) years ago,
and when the Jameco rep talked the owner into putting in a rack of
electronic Jim-Pak parts, that was what turned the corner. He got rid
of the books and went into electronic surplus and new parts. It's not
the largest place you've ever seen, but he's got a broad assortment of
stuff. Quite a few ancient computer parts (8" floppy drives, S-100
bits, etc.) as well as a decent selection of new Rs, Cs and Ls. He's
usually got what I need (75%).

stock distributors have a fair amount of surplus on display or in a side
room. Components only for the most part.

* Radar Electric
Seattle, by the Seattle Center. Best place in town for electronics
tools.

* Supertronix
in Kent, by the Boeing Aerospace facility, a couple miles west of
Boeing Surplus. Sort of a Radio Shack on Steroid, similar to
Active Electronics.

* Electronic Supply
just west of the I-5 Freeway on North 45th St., west of the
University of Washington. Consumer Electronic Repair parts,
Batteries.

* Electronic Supermart (The folks from United Products)
north of the city, in Lynnwood, southwest of the Alderwood
Mall.
More new parts, less surplus than the old United Products.

* Amateur Radio Supply
north of Boeing Field on Corson Ave. A little bit of used Ham
Gear.

There are also about 4 or so Ham Swapmeets a year in the area, a
regular commercial monthy computer swapmeet that rotates between 3
different sites, and a couple of guys that sell test equipment out
of
their garages. (Anyone know if the guy that sells old Tek stuff in
Redmond or Woodenville still has a store?)

---TUKWILA

(From Keith Lofstrom)

There is a semi-interesting used software place named "Bruno's" in
Tukwila, at the south end of Seattle; worth a stop on the way
through.

If your travels take you 25 miles south to Tacoma, there is a
surplus
store (Electronic Dimensions?) with a lot of military and RF test
equipment - I found the owner a little disagreeable, though, so I
don't have more info.

I have second hand information about a place up in Snohomish county
called Electronics Mall; when they were down near Lake Union, they
had
appropriately decaying electronics gizzies. It is sad that they
moved,
because they were a couple of blocks from Archie McPhee's on Stone
Way, the best Inappropriate Toy Store in the world. Since I bought
"electronic surplus" there (a foam plastic rock that makes the
sound
of shattering glass when it hits something) I will mention Archies
as
a source of surplus. You need a glow-in-the-dark plastic slug,
don't
you?

WISCONSIN

---KENOSHA

(From Dennis Doonan N9VSL)

Chester Electronics
Sheridan Rd
Kenosha, WI 53140

Repair parts for radio/tv repair shops. Some consumer goods. There is
still a large stock of NOS parts and connectors.

---MILWAUKEE

(From Dennis Doonan N9VSL)

American Science & Surplus
6901 W. Oaklahoma Ave
Milwaukee, WI
Tel: (414) 541-7777

Surplus military, electronics, optics, educational, and misc. odds and
ends. It is easy to spend hours here just looking through the rows of
stuff. They even have a tent sale every year.

---RACINE

(From Dennis Doonan N9VSL)

Superior-Racine
1006 State St
Racine, WI
Tel: 632-5142

Old fashioned radio/tv repair parts store that never made it into the
1990s. Repair parts, surplus "stuff" some consignment, and lots of the
little odds and ends you need for a repair and or restoration
project.

---WEST ALLIS (MILWAUKEE)

(From Dennis Doonan N9VSL)

Radio Recyclers
7730 W. NAtional Ave

West Allis, WI
Tel: (414) 771-7121

A great place. Worth the trip. Ever changing stock of used amateur radio and SWL gear. He maintains a want list, backs his equipment with
return policy and 30 day warrenty. Everything from near new Japanese
rigs to Collins, Drake, National, etc, etc. Also parts, accessories,
tubes, and "gizmos".

THESE STATES HAVE NOTHING!

5447. DVK software available

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: Stu Olson <solson@usa.net>
Message-ID: <74fdck$1ri$1@oak.prod.itd.earthlink.net>
Source record: 76158

Just in time for the next meteor shower, or CHRISTMAS!!!!

If you are not happy with the current offering of software voice keyers, how about one that was designed from the ground up with MS operators, contesters, and ragchewing in mind! If your PC has a Windows compatible sound card, its time you try this digital voice keyer. (Heck, one of the users even figured out how to do MS CW skeds with it.)

Check out http://home.earthlink.net/~n7qjp for the details. You'll be glad you did!

New version released today, version 1.2.15.

Next release will integrate completely with FT-Manager CAT control software. Release date later this week.

How about a Heath Cantenna??? Always worked great for me. I've
got a couple of spares if you want one. Craig

5449. Dow Key type antenna relays f.s.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-06 00:00:00 UTC
From: Ron Ostman <w0nyq@minntaccdp.com>
Message-ID: <74flge$d8s$1@news.ispn.net>
Source record: 76160
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

For Sale:

2 ea. Advance Electric and Relay Co. antenna relays w/ SO-239 connectors and
115 vac coils. Thes units look basically the same as the Dow-Key units
except are a bit larger (better built, in my opinion).
Also have auxilliary contacts.

Will sell for $35 ea. plus shipping or $65 plus shipping for both.

Ron Ostman, W0NYQ
Mt. Iron, MN

5450. Panel Meters f.s. - Triplett 0 -1 mA

You probably need to look up those Al values again. In general, ferrite
cores have higher permeability than powdered iron. I know of no reason
performance wise why you would ever want to use powdered iron for anything
except an RF choke that has to have DC current going through it, where
the higher saturation flux density of powdered iron can be an advantage.
What makes ferrite better is higher permeability and lower loss. The
higher flux density of iron is only of interest at DC because the core
loss causes the toroid to overheat with RF excitation before it saturates.
If one of you powdered iron enthusiasts out there (I know you're there)
would like to tell me why I should ever want to use powdered iron, I
will be happy to be corrected.

5453. Updated subminiature tube AM radio, peak current limiting for rectifier

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-07 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseF3KJy6.8sF@netcom.com>
Source record: 76164
Cross-posted to: rec.antiques.radio+phono,rec.audio.tubes,rec.radio.amateur.homebrew

I updated my AM radio using submini tubes. Specifically, I inserted an 18 ohm resistor in series with the rectifier cathode to keep the capacitor charging current peaks below the max peak current rating of this tube. If you don't you will quickly wear out this tube, as you blast the cathode coating off the cathode from excessive peak currents. Generally, vacuum tube rectifiers can take peaks about 5 times their continious rating.

Powdered iron has less of a tempco and gives better frequency stability in VFO designs. For those of us that don't build DDS or PLL VFOs, and have to use a core material at all, powdered iron gives much better results.

I'm sure you've wondered why several companies have been quite successful in selling powdered iron cores for many years. If they had no utility or advantages over ferrites, they would have gone the way of RTL and the germanium transistor. Here are some of the reasons they haven't.

I can easily get a Q of 200-250 with small (0.375 - 0.5 OD) inductors in the one microhenry range (that is, a few hundred nH to a few uH) at HF using high-frequency powdered iron (types 2 and 6 -- Carbonyl E and SF -- relative mu of 10 and 8.5 respectively). I use these materials exclusively for lowpass, highpass, and bandpass filters, tranmitter output networks, antenna matching, and any tuned circuits at HF. (I also use them at VHF.) Type 6, in particular, has a very low temperature coefficient -- much lower than any ferrite I know of, and I use it for VFO tank inductors. (I've made many simple Hartley oscillators having a warmup drift of about 200 Hz at 40m without any temperature compensation. This drift is due almost solely to the inductor, wound on a type 6 powdered iron core, and could be compensated quite easily.)

I've used low-frequency powdered iron toroidal cores for RF chokes. A gapped ferrite core could be used for this, but a toroid is convenient, inexpensive, and self-shielding. The same goes for inductors in low-frequency power circuits such as switching power supplies, although I've tended to use gapped ferrite pot cores mostly for this because of their availability at the companies where I've worked.

I'm not a "powdered iron enthusiast" any more than I'm a "ferrite enthusiast". Each has its own advantages and disadvantages, and one is frequently better than the other for a given application. As an engineer, I try to choose the best component for the job.

Roy Lewallen, W7EL

5461. 2SC1969 datasheet needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-07 00:00:00 UTC
From: IW2KPU <iw2kpu@radionostalgia.net>
Message-ID: <74g8mufin1@fe1.cs.interbusiness.it>
Source record: 76172

I need the datasheet of the 2SC1969 RF transistor.
Best if the data are in the .PDF format.
Thanks in advance.

iw2kpu@radionostalgia.net

OK this is outrageous and totally out of line!! Yes I konw, but who can resist help a woman in distress??

As I have two hobbies, ham radio and dogs, you might have seen my comments about electrical fences and dogs.

Right now a good friend (who accutally teached me everything I know about dogs) needs our help.

Her dog is on an "virtual dog show" and needs as many votes as possible!

IF you help us now, I promise to help you guys out, answering as many queries I can, and then some!

PLEASE follow the instructions (if you have a minute left over):
go to

http://www.alltomhundar.com

Down on the left hand corner you will find:
" R�sta p� din Favorithund i Utst�llningen! " (vote for your favourite dog in the show)

Cklick the mouse

Please choose from the pull down menue:
Dog nr 18 Brainwaves Evita! (A.K.A. LISA)

Done

You can only do this once from each computer.

Once again, remember if you help us out I will certainly help you out in the future!!!

Cheers

5464. How to cut plexiglass

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-07 00:00:00 UTC
From: william.miller@lrh.net
Message-ID: <912990813@lrh.net>
Source record: 76175

-> Hi "Brewers"

-> I need to cut three pieces of 1/16" plexi into strips 3/8" x 10".

-> Any advice on how to produce very clean cuts?

-> Rick, W1TY

Sawing makes a mess. Best way is with a plexiglass
scoring knife. I got mine at HOME DEPOT. It works
fantastic! You score both sides and then break it cleanly.

Bill K1IBR

5466. Guardian Series 200 relays f.s.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-07 00:00:00 UTC
From: Ron Ostman <w0nyq@minntaccdp.com>
Message-ID: <74gqarehu1@news.ispn.net>
Source record: 76177
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

For sale:

I have quite a few new-in-box Guardian Series 200 relays. These were the "roll-your-own" modular type with removable coils and contact assemblies. I have both 24 vdc and 120 vac coils available.
Contact asseblies can be stacked to make whatever configuration desired.

These relays were original equipment in some Ham gear and were popular with homebrewers because of their versatility.

$15.00 ea. plus shipping

According to Amidon, ferrite saturates at 2000 gauss and powdered iron saturates at > 5000 gauss. In large-signal work where small non-linearities are important, iron is preferred.

One example is in the lowpass filters for solid state SSB PAs. If we need a certain value of inductance, a small ferrite core with few turns can be used but will have high flux density and will tend to reach saturation and become *too* nonlinear. A large iron core with more turns is needed, so flux density is smaller, saturation level is much higher and is clearly a much better choice. Iron is also nonlinear, but much less so.

In small signal applications where small size is important, ferrite is used a lot.

5468. Re: How to cut plexiglass

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-07 00:00:00 UTC
From: jstrohm@texas.net
Message-ID: <74gvp8oqa1@nnrp1.dejanews.com>
Source record: 76179

My dad passed along a tip for cutting plexiglas. It made me slap
my forehead and say "Doh!"

Use a coolant/lubricant fluid on the blade when cutting.
He's had good results with WD-40, 3-in-1 oil, motor oil, and
plain old water. Your only concerns are -- don't get the fluid
inside your saw, and use a fluid that won't damage the material,
and that can be cleaned from the material without damaging it.

The reason most people have trouble cutting plexiglas and other
plastics is that friction causes the saw blade to heat up, and the
chips melt instead of being ejected. This answer was so simple
that it was easy to see why nobody's thought of it.

Naturally, a water-cooled power saw for ceramic tile would be perfect.
If it'll cut a tile, it'll sure cut plexiglas.

And yes, yesterday you could have seen ne trimming Christmas candles
in my power miter saw using an abrasive metal-cutting blade. Melts
right through 'em -- but the the 40TPI wood blade makes a neater cut.

---------- While I am far from an expert on this stuff I can suggest that in addition to what has already been written to you you can anticipate potential sources to include transformers or motors in a neighbor's house. There ws an article in QST about 11/2 years ago that described various episodes of trouble shooting this kind of stuff. The article is less than two years old for sure.

I hope I have the right news group and if not please offer any suggestions.

I have a problem keeping my dog off the carpet and was thinking of possibly using an Electronic Dog Fence under the floor in the doorways to the rooms that he is not allowed in. In the true spirit of a hobbiest and Ham, I would like to build something along the same line. I am a Tech with my own service shop. What I am looking for is some understanding of how Electronic Dog Fence work. I have my suspicions but any help would be appreciated

Please email me at dberry@wcl.on.ca as I don't always have time to watch this news group.

Thanks Again Doug VA3DMB

That's OK, as we don't always have time to act as unpaid private
engineering consultants. Ask on the discussion groups, and stick around
to participate in the discussion. That is why they are called
"discussion groups."

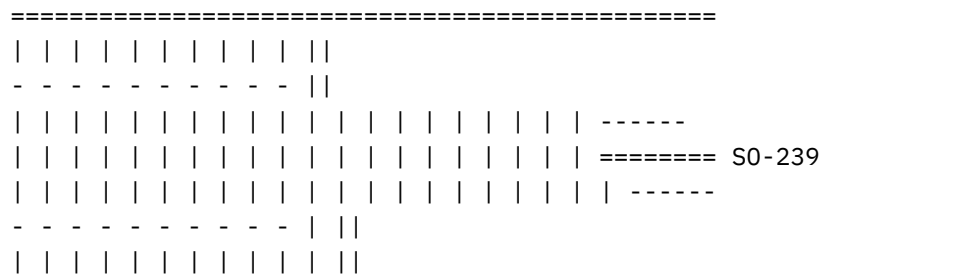
Colin,

You probably can't find any designs because they are rather easy to make. The key to making a good one is to make sure you use carbon composition resistors. There are a lot of high power, low resistance, resistors out there but they are usually wire wound and not suitable for a non-reactive dummy load.

About 15 years ago I bought a Heathkit HX-1681 CW transmitter. Fully loaded it runs about 160 Watts input. For testing I needed a dummy load. I went down to the local radio store and bought a box (66) of 3300 Ohm - 2 Watt resistors. When you buy a bunch, they are pretty cheap. Then I took two 4" x 5" pieces of single sided circuit board, drilled a lot of holes in them, and then mounted and soldered all the resistors between the two boards. Then I attached a SO-239 connector. Below is kind of a crude picture. If you use a fixed width font you should be able to get the idea.

copper side of board



==========
copper side of board

Since I initially built the dummy load, I tested it with a
variety of transmitters and bridges, from 1 to 500 MHz and
always got an SWR <= 1.2:1 . I've even tested it against other
commercial dummy loads and found it to be quite satisfactory.

This configuration should handle 120 Watts (66 x 2) continuous
and easily twice that for intermittent service, i.e. SSB. It is
a good idea to put some kind of a cage around it, because it
will get warm at high power levels.

Even though I built this thing 15 years ago I still use it
and the HX-1681.

Hope this was of some help. If I can be of more help, like
drawing a better picture, let me know at the email address
below.

Hi,

I recently purchased a 40 meter QRP rig that I would like to take on the road with me. I was wondering what type of antenna would be best to either bring along, or utilize something already at the motel.

I am planning on building a low power antenna tuner for the rig.

Any suggestions for an easily portable 40 meter antenna for QRP?

Thanks for your help.

Here is something else you can do. I had forgotten about it till today.
If your transmitter is in the 100 watt class, you can use a 100 watt
light bulb. It will have an impedance that is good enough. I used it for
tube type transmitters, but I havent tried it on solid state units. They
might require more accurate loads.

>SF -- relative mu of 10 and 8.5 respectively). I use these materials

Yes, I used to build inductors like that too. But then I found that
you could get twice as high a Q with Fair-Rite 67 matl in the sizes
you quoted. (Mu of 40).

>also use them at VHF.) Type 6, in particular, has a very low

Good point. I hadn't thought of that (not being a VFO builder).
At VHF, I have found that those little spring inductors from
Coil Craft have a very low tempco with an air core.

>I've used low-frequency powdered iron toroidal cores for RF chokes. A

I've tried powdered iron, moly permalloy and ferrite in switching
supplies and the ferrite has much lower core loss.

I had this problem and used a Radio Shack personal infrared proximity alarm. He loved to go in one area and an alarm going off every time he was there was a great deterrent. Not a bad piece of technology for around $20!

I have the following 5-packs of NOS tubes on eBay - they are going very cheap. Last day of auction!

If you are intersted, please check them out:

5-pack of 5763 driver tubes
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=46566004

5-pack of 6BH6 IF amplifier tubes
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=46567843

5-pack of 6AK5 RF amplifier tubes
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=46569320

Thanks,

Al - K8EUR

The classic 100-200 watt dummy load of 50 ohms impedance is a 200 watt lamp. It works out to right close to 50 ohms, and for freqencies below vhf, it works fine as a dummy load, is cheap, and you can see the power transfer into the load, for tuning. I have been using them for 30 years, on everything HF, with no problems. Use a good porcelain base at full power, since the plastic ones tend to heat if the keydown time is very long. Series/parallel a brace of them and you have a fine 1kw load. Solder up a short pigtail with the proper RF connector for your rig, and away you go!

It is one of the best kept secrets of the fancy painted glowbar dummy load sellers.......(:+}}....

Solid state does fine with it. A 200 watt lamp is probably more closely aligned with 50 ohms. There is a fine paper by John Nagle, in one of the older CQ/73 or such, and several in older QST's that give the specifics of the heating constants and load factors and resulting RF impedances.

At HF it really does not matter very much. At VHF or UHF it is another story, and probably not good to use there, unless you know what you are doing.

You are right, though, it is forgotten lore... but very cheap and very useful, even today!

Caution.... they do get hot, and will radiate slightly. You could mount it in a tin can and make it a black body radiator of sorts, or put holes in the can so you still can see the RF transfer and watch for the nice glowing peak loading. An old paint can will work, as will an old tin box of any sort.

The practical mismatch of such a load is mostly insignificant at HF, and it should be less that 1.5:1 under most conditions, which is fine. Even transistor rigs handle that fine.

> Marc

Not any more. In the old days there were a couple of companies making
``tubesters'' and such called things that were plug-in replacements for
many tubes. There were several articles in QST/CQ/73 on building them
yourself. Noone makes them anymore, commercially, that I am aware of.

I solid-stated an old Hammarlund RBG (HQ-125) that way, when I was a
novice and ran it off 28vdc. It was fair to good, redone, but not
any better than with a good set if tubes.

Generally, take an old tube socket (or a better substitute are old
plug-in relay cases of the octal type), and drop in a 40673 or
equivalent FET, and bias it correctly so it does approximate the
required tube function. Converter tubes are a little more complex
in that you have to set the oscillator with one transistor and the
mixer with a second transistor. The audio is relatively simple
with discrete or IC components.

But, you would be better off running it with tubes, and probably
redoing all the bypass caps and series dropping resistors. The
older tubes are still quite common, and you won't materially
do better with transistors at HF using the old designs.
You could completetly redo the IF or AUDIO strips, but that
would be a waste of a fine old radio, unless it was already
in torn up shape.

Eventually, I went back to using tubes, because it was more
controllable that way. FET's were too bloody unstable.

I did a Collins R-392 that way, using Vector plugins, and it
was more controllable, generally, and a bit less noisy. That
was because the Collins design had much better shielding.
The old Hammarlunds and early octal things will tend to be
rather unstable as the gain is increased, because of stray
feedback loops, and not so good shielding.

Good Luck

Bob/NA4G

Sorry for offending some people My intention was never to shock or hurt the dog just to have some sort of buzzer or something to scare him. The Dog is an important part of are family it's just that he doesn't listen very well. My understanding of an Electronic Dog Fence is that it is but under the grass around your yard and when the dog comes close to the edge of the property a buzzer goes off in a small box on his collar. My idea was to use it in the doorway to the living room. What I was trying to find out was how they work.

Again sorry for offending anyone and thanks for the constructive help I did get

A couple of notes on light bulbs.

First, since a light bulb is not a resistive 100% shielded load,
it can (and WILL) radiate RF. Second, since its electrical properties
can change dramatically when excited, you risk damaging the transmitter.

An acquaintance loaded my Invader 2000 into a lightbulb. The 4-400 PA finals
were not damaged, but the arc-over killed the 12BY7 driver and both
6146 exciter finals.

He didn't say whether he worked any rare DX with the lightbulb antenna....

Hello
I have a couple hundred feet of cable TV hard-line. 3/4 & 1/2 inch O.D. I had an old 73 magazine that showed how to make matching transformers for each end to bring it down to 50 ohm. I can't find the magazine anymore. I have since found a old HAM RADIO magazine that covered the same subject. In the 73 mag I seem to remember that they used 3/4 inch copper pluming pipe for the outside and 3/16 inch brass tube for the center conductor. In the HAM RADIO article they use 1/2 inch copper pipe with the for mentioned center conductor. Also they didn't have any measurements for 440. The length of the copper transformer is about 20 some inches. I have to go look at the magazine to be exact. Has any body built these and do you have the dimensions for the 440 MHz transforms. I know how to do the hardware attachment I'm just not sure about the lengths. They both show the math but believe me it looks like Greek to me.

---------- You did not say if the sound occured only when transmitting or only when receiving or both or even if when the radio is turned on.

In any event I suggest you find a garage setting where you can be in as dark a place as possible and have the hood up and have the situation repeated (transmitting or whatever the circumstances are) and look for gap jumping voltage. If you are able to get a visual on the location then you are in better shape to fix it.

5501. How to mount toroids securely when doing dead-bug construction?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-08 00:00:00 UTC
From: nicholas charles caruso <caruson@certco.com>
Message-ID: <366D81DB.1F308E89@certco.com>
Source record: 76071

I've been building a VFO dead-bug style on a piece of fr-4 single-sided pc board. It works fine, but the wire used to wind the toroid in the tank, and in interstage transformers in the buffer amps, is so flimsy that I'm fairly worried about the mechanical stability and durability of the toroids.

I am thinking about making a PVC center post for the toroid, and then epoxying the post to the PC board.

Would this be electrically ok? I could get a piece of teflon or similar, if that would be better.

Anyone have any suggestions?

I dont see why your Idea woulnt work fine. Pvc isnt the best dielectric, but since a torroid has most of the field inside the torroid, it shoulnt matter too much. Here's another Idea which would allow you to remove the torroid if you ever needed to. Drill the board and put an insulator if need be (maybe automotive gasket material?), then use a small screw to mount it. This may not work on tiny torroids.

Most of the field is inside the toroid, as Don says, but it's still a good idea to avoid getting poor dielectric really close. What you end up with is lossy turn-to-turn capacitance which lowers the Q. In most applications, this might not make much difference, but it can degrade the temperature stability of a VFO tank inductor. In experiments I ran years ago, I found that a lot of common materials, like RTV and epoxy, will degrade the Q. A non-acetic acid-curing RTV was a lot better. This kind of RTV is now available at hardware stores as GE Silicone II. I haven't tested this particular brand, but think it's likely to be better than the acetic acid stuff for this application. I'd mount the inductor vertically, held down with a dab of this RTV. You can use any number of other mounting arrangements, but I'd try to keep anything except a good dielectric like Teflon or styrene from being in direct contact with a lot of the turns.

Message-ID: <366D900E.1C5FF28A@usit.net>
Source record: 76075

I am using a muxed display, and I dont have any data on the display units. They seem to be bright enough if I use a 10 ma test current from a dc supply. If I use 7 digits in a multiplexed mode, dont I need to have a segment current of 70 ma to produce the same brightness? Does anyone know what a rough current limit is for such devices? These units are surplus, and are about .4 in. digit height. I have several different types in the junk box, and they all seem to have about the same sensitivity.

Granted. If that is problematic and usual power levels on short
leads, put it in a box.

> Second, since its electrical properties
> can change dramatically when excited, you risk damaging the transmitter.

I have heard that, but never run into that problem in 30 years.

> An acquaintance loaded my Invader 2000 into a lightbulb. The 4-400 PA finals
> were not damaged, but the arc-over killed the 12BY7 driver and both
> 6146 exciter finals.

What arced over? If the final were a dead short, that would not be
materially reflected back onto the driver tube. It sounds like
another problem may have occured. Were the drivers and exciters
properly tuned up first? It sounds more like offresonance in the
driver and exciter stages, and they did not transfer power correctly
to the final.

What size light bulb was used? If large rigs are going to be run
into light bulb loads, the Navy used to recommend 500 watt Mazda
lamps on the 1kw rigs, for example. Obviously, scale accordingly.
On the average 100 or 200 watt rig, a standard 200 watt lamp works
fine.

> He didn't say whether he worked any rare DX with the lightbulb antenna....

The best I have gotten at 250W into one is about 50 miles......(:+}}...

If I just want to quickly QRP the locals, running into the light bulb
load leaks just enough for local QSO's without running an antenna.

5507. Ideas for my homebrew rotator?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-08 00:00:00 UTC
From: Terry Gaff <shbcommm@indigo.ie>
Message-ID: <366D9BAC.59DAC7A7@indigo.ie>
Source record: 76077

Hi all,

I'm in the middle of building my own light antenna rotator and I am considering some options to allow some sort of system whereby I can tell what direction the antenna is pointing. One option is to use a potentiometer in the unit and use it to vary volage as the antenna rotates, it could be read on an analogue AVO meter with a N/S/E/W scale on it's face. Can anybody give me any other ideas ? I've also considered an optical encoder but they're a bit expensive.

Thanks in advance.

Terry Gaff

5508. Re: How to mount toroids securely when doing dead-bug construction?

>
> I dont see why your Idea woulnt work fine.

I agree, and here are some other things I've used at home and at the
office:

1.) Nylon hardware (software?) -- 4-40 nylon slotted head screws can be
used
without washers to hold down small toroids. Use a metal nut and
lockwasher on
the back side of the circuit board.

2.) RTV -- put down a blob of the stuff and mush the toroid into it;
then squish
some more RTV over the whole mess. In a day, you can cut away the
excess with
an exacto knife. (Actual name is Dow Corning DC-732 sealant.)

3.) A dielectric spacer, glued to the board, then glue the toroid to
the spacer.
Use 5-minute epoxy or some other 2-part epoxy with resin and hardender.
Avoid
crazy glue. Alternatively, glue the toroid to the spacer first. You
can make
the spacer with copper lands to solder the wire to.

4.) Dielectric spacer underneath the toroid, and a fiber washer or
spacer on top.
Screw the whole thing to the board with a small (2-56) metal bolt and
nut, or even
use a sheet-rock screw.

Whatever you use, you should stake the skinny wire you wound the toroid
with by
gluing it to the board so it doesn't flap in the breeze to stabilize the
frequency of the vfo.

> > Colin
==========
A simple but effective HF Dummy Load can be made as follows.

Ingredients :
1) 20 pcs 1KOhm-2W metal or carbon film (or composite carbon)
resistor , tolerance 5%.
2) Round tin container previously holding paint ,cocoa or whatever ,
size approx 4" Dia x 5-6" tall
3) Metal jam jar lid which is slightly smaller in diameter than the
circular opening of tin 2) .
4) SO-239 socket with square mounting flange having 4 holes
5) 2 pcs Metal stand-off approx 1" long with tapped holes and screws
at both ends
6) A 6 " length of thick single copper wire (up to 1/8 inch dia) or
multi-strand wire stiffened by soaking with solder.

Work :
1: Line inside seams (ie bottom circular and vertical) of tin 2)
with a little 2 component expoxy adhesive to prevent any future
leakage when tin is filled with oil

2: Fit SO-239 socket in centre of removable lid of tin 2) and
fix diagonally with the 2 metal standoffs 5) at underside of lid.

3: Drill 3/4 inch centre hole in jam jar lid 3) and subsequently
drill 20 holes just large enough to pass one of the wire ends of the
resistor 1) . The 20 holes to be equally spaced in a circle at max
diameter ,drilled in the flat face of the lid . Now tin the jam jar
lid in the area around the 20 holes just drilled
Now drill 2 holes in the jam jar lid in such a way that when fixed to
the 2 metal stand-offs the jam jar lid is concentric with tin lid
/SO-239 socket . The jam jar lid is now positioned parallel to the
tin lid with its SO-239 socket. The 2 lids are kept at a distance
from each other by the 2 metal stand-offs .

4: Solder thick (stiff) copper wire end to centre pin of S)-239
socket ,such that this wire is protruding through centre of jam jar
lid ,without touching it.

5: Now take the 20 resistors, shorten the leads in such a way (the
shorter the better) that one end is soldered to the jam jar lid with
the resistor leads each just protruding through one of the 20 holes

for easy fixing.

6: Now trim the stiff copper wire as well as the free resistor wire ends in such a way that all the 20 resistors can be soldered to the stiff copper wire , again keeping the wire ends as short as possible but without the resistor bodies touching each other. All the 20 resistors are now forming a cone .
Note: Before soldering the 20 resistor leads to the copper wire end , you can tie the leads by means of a few thin copper wire strands.

7: If you bring the unit just made inside the tin ,ensuring that the tip of the resistor cone does NOT touch the inside of the tin , you have a (strictly speaking) 1000/20 = 50 Ohms , 20 x 2 = 40 Watts dummy load.

The power rating can be readily increased by filling the tin partly with oil (I use ordinary motor oil) such that the resistors are fully immersed . If applying 100 W RF to the dummy load it takes quite some time before the tin gets warm. Obviously with a larger tin ie with more oil, the heat capacity ,hence power rating of the dummy load ,can be increased.

I have used the dummy load as described above since 1985 , never changed resistors or oil .
From time to time I measure the resistance (again just a few minutes ago) which remains between 50.6 and 50.9 Ohms The carbon film 2W resistors are as supplied ie have not been treated with varnish .

SWR remains 1:1 up 14.350 MHz ;at higher frequencies there is a slight increase .....to 1.2 at 29 MHz

I have a similar dummy load with the resistors fitted between 2 circular discs of expoxy perv board ,(resistor leads cut-off after soldering). However I haven't used it with oil ,since it's only used for low power .
This dummy load is also fitted in a tin with the upper disc connected to the stand-offs and the lower disc connected to the centre of the SO-239 socket via a thick copper wire . This arrangement is somewhat more compact.

On various occasions I came across heated discussions on which type of oil to use . Some say that motor oil should NOT be used especially with carbon composition resistors because certain chemicals (additives) would ruin the resistors and that overall ,transformer oil is better /essential . Nevertheless when using carbon composition resistors I would give them a coat of polyurethane (high temperature) varnish and try motor oil ,since I can't get transformer oil easily here in the north of Scotland. After all , Ham Radio is a hobby .

Hope you find the above info useful.

==========
Connection in series is OK but please fit across each capacitor say 2
pcs 47 K Ohms resistor in series to ensure that each capacitor takes
half the overall voltage . Check power rating of resistors .
If total voltage is 800 V each of the 4 47K Ohms resistors takes 200
V . This means their power rating needs to be not less than 2 Watts ,
to be on the safe side.

==========
Keith ,recently on the [AMP] reflector I saw advice ,how to determine
the power rating of a transformer for 50-60 Hz

Connect a variac (variable auto transformer) between AC power supply
point and primary of transformer.
Put an AC CURRENT meter across the secondary winding. The secundary
winding is now basically shorted (ie the load resistance is that of
the current meter).
Now increase output from variac from zero to a level that the current
meter in the secondary gives a reading to be the expected max.
current rating (which can be estimated from the secondary winding
wire diameter).
If the transformer remains cool ,increase the variac output bit by
bit giving the transformer temperature adequate time to stabilise.
When the transformer gets somewhat warm, the current read is the
max current which can be used for continuous operation .
I agree this is not a very scientific method ....but practical it is.
A good method to know what rating you can expect from any power transformer.

You can use a plate with holes in it and an optical coupler and at the shack
a simple up down counter from a couple of ics.

Really wild idea, take the guts of a mouse and feed it into a computer via
the serial port. With the old computers selling fro almost nothing, you
could get a xt or a 286 for $ 5 at a hamfest and a mono monitor and
keyboard. Not very much cost at all and you can use it to aim at the sats
too if you put in an azel rotator. Also check out the Fodtrack program and
interface on the amsat.org files for a cheep interface.
Also you could use the game input if you still want to use the pots at the
rotator.

Uh-oh... I thought we all new this was not good enough. The light bulbs
power rating is only valid at around 60 hertz. It impedance is no where
near 50 ohms resistive, unless you're extremely lucky. It is better,
MAYBE, than operating your tube rig into an open. It most likely
resembles a short at radio frequency. Maybe some day I'll hook up a
light bulb to a network analyzer and see what the Z really is!

If you're recieving radiated noise, you'll have to shield/filter at the
source of the noise. Sparks are very broadbend and difficult to fix.
Try a common mode choke (several turns of both power leads around a
toroid, in the same direction) right at the radio. Make sure that the
radio has only the power lead connected to the chassis. You may also
try a common mode choke on the antenna lead. good luck

The core cross sectional area is related to how much power the transformer can dissapate. From this and the secondary wire size in enclosed area, transformer
effeciency, and secondary voltages you should be able to calculate the current.

See Section 3-6 (Page 3.25) Transformers in the Radio Handbook 22nd Ed by William I. Orr, W6SAI for some help.

You will probably need to go to a library and get a book on transformer design to show the power per cross sectional area of the core plus current ratings for enameled wire for open air and enclosed.

Not a problem if you use a 100W network analyzer.

If we assume that the filament thermal time constant is long enough,
after the temperature is stabilizd, the filament
looks like a resistor. Ohms law will tell you the effective resistance
versus power as a function of the light bulb size. You can estimate
the inductance of a straight wire that's as long as the loop thru
the bulb in series with the calculated resistance. Or you can actually
measure the inductance.

Or if you only care how good it is as a dummy load,
just can take the lazy ham's (my) way and stick an SWR bridge in
the line and measure it!

Be advised that a light bulb sucks for anything that requires a
quantitative measurement because of it's sensitivity to power.

Wanted:

Audio transformers for regenerative receiver projects - anything from 2 -1 to 10 -1 impedance ratio would be fine. Older ones with labelled terminals preferred but will consider anything.

Thanks,

Ron Ostman

Here's another possible method of evaluating transformers. A well designed transformer will typically have approximately equal core loss and copper loss. Plug the transformer in to the design primary voltage and leave the secondary unloaded. Measure the core loss with an AC wattmeter. Measure the resistance of the windings and you can figure out how much current can be drawn to equal this same loss in terms of copper loss.

If you don't have an AC wattmeter, you can measure the temperature rise from just the core loss with a thermometer and then compare that to the temperature rise from your proposed current draw.

Keep in mind that there is no fixed limit to how much power you can get from a transformer; it just depends on how much heat you can dissipate. The trouble is that you don't know what the temperature rating of the insulation is on an unknown transformer, that is why the core loss is a good indicator, because the designer chose the number of turns to get that core loss. Obviously, he felt comfortable with the resulting temperature rise. BTW, core loss is independent of load.

You can't conclude much from core volume or cross sectional area in terms of maximum power. Yes, generally the bigger the core, the higher the power, but for the same core, the power could vary by a factor of 3 depending on various parameters.

Note that the amount of power a transformer can put into rectifier driving a capacitor input filter is considerably less than it can put into a resistive load, or a choke input filter.

I built the Ramsey 2M kit a couple years ago. Works OK for a
simple rig. The feeling you get when it works is quite fantastic.
I could kerchunk a repeater, but didn't get anyone to get back
to me. I had thrown in a 'dip switch' just to set frequency easily
while I jack around, and started flipping through frequecies.
I tried 52 and it was dead, then went to switch to something
else, and got someone by accident. Once I figured out what
the frequency was (it was wierd simplex) I called out and the
guys came back to me. Turned out he had a HUGE beam,
and was trying to work someone about 15 miles from me. He
was over 60 miles away. Anyway, the three of us chatted for
about an hour, a lot about the kit.

Normal contacts aren't that much fun.

I have a S10 pickup and a Geo Metro, both have Icom radios in them. The radios have both hot and ground wires ran directly to the battery. I changed all plugs (I used resister type), plug wires, dist. caps and rotor buttons but I still have a motor noise that sounds like fire jumping from a plug wire. It isn't a whine just a poping sound. I had a Yeasu in the truck that did the same thing so I know it isn't because the radios are Icoms. Is there a filter or something I can do to stop the noise? Also the car has a mag mount 5/8 wave and the truck has a 5/8 wave mounted directly on the cab. A 1/4 wave ant. had the same noise. Any help will be appriciated.

Q of 400-500 in that inductance and frequency range? I'll have to get some of that material and try it. Sounds great! The one curve in my Fair-Rite catalog, with 9.5 mm OD toroid but unspecified inductance, shows only about 270 at 10 MHz, but maybe it gets better at some inductance ranges. The specified tempco of that material of 0.13% (1300 ppm) per degree C is a whole lot more than my favorite powdered iron, type 6, at 35 ppm. In fact, the ferrite tempco is high enough that it might present a problem in high-Q filters or tuned circuits. Type 68 ferrite looks interesting, too, with listed Q of about 340 at 10 MHz (again with an unspecified inductance) and tempco of 600 ppm/degree C. Still much too high for VFO inductors, but maybe good enough for reasonably high Q filters. I'll have to run some numbers to see if flux density would be a problem in transmitting applications like antenna matching components or transmitter output networks at the levels I usually operate and core sizes I tend to use.

Oh, one additional application for powdered iron I didn't mention. Low-frequency powdered iron cores are sometimes used for power supply decoupling, again because of their ability to handle a large DC component. Solenoidal ferrite-cored inductors are also used, but the self-shielding property of the toroid is sometimes advantageous.

I hadn't fooled with the very low-permeability ferrites, and I see it's time to do some experiments. Thanks for the tip.

I second that. There's a group of folks in your country that have a whole lot of fun with amateur radio and with building, the G-QRP Club. I heartily recommend you get in touch with them. Start with George, G3RJV. His email address is g3rvj@gqrp.demon.co.uk, telephone 01706-31812. He's located in Rochdale, near Manchester.

The G-QRP Club actually has members all over the world, and its excellent magazine, Sprat, is always full of good projects of all levels of complexity. I highly recommend it to anyone interested in QRP, building, or both.

> 28V?

The simplest answer is to use a 741 op-amp with a LED on the output.

One input is fed from the suppy line via a resistor with say a 9v
zenner to earth.

The other input is taken from a preset pot wired across the supply rails.

Set the supply to 28 volts and adjust the pot so that the LED is off.

Set the supply to a lower voltage and the LED should light.

If the results are the opposite of these then reverse the wiring to
the two input pins.

Hi:

Epoxy is ok. PVC is not a great coil material, but ok to hold it.

You can purchase some polystyrene coil liquid to just put on to hold it. I do not remember the stuff, but use it all the time. Also, shoe goop works fine (although my wife hates the "skunk" odor.

Epoxy is too much work and takes too long. Most of the clear glue is fine. Also, in a pinch, clear finger nail polish is ok.

Easier said than done. Many are limited as to what they can put up in regards
to HF antennas. After listening for awhile, they'd probably be bored with HF
anyway.

I tend to disagree. 30 years play indicates otherwise, in my hands.

But, if you happen to put one on a network analyzer at power, I would
like to have some corroboration of what I use. Try a 200w, and a 150w
bulb. My experiences suggest that the 200w is fairly close to 50 ohms
and the 150w fairly close to 75 ohms. I don't have any good laboratory
data to corroborate that, though, other than what is published here
and there. I can provide references if you need them, maybe over the
weekend.

The actual resistances may be +- 20% but that tolerance is entirely
sufficient for amateur use.

Cold, the resistances tend to be low, but warmed up to a red heat or
above, they seem to act quite close to a standard glowbar at HF, stray
inductances aside, or mostly insignificant at those frequencies.

> Jim Muehlberg Don't forget the reason for the season!
> muehlberX@plains.nodak.edu

I would like to see any data you may be able do obtain.

The thermal time constant in my hands is around 0.1 seconds to 0.5
seconds. That is adequate for almost anything, unless you are pushing
a rig to the design maximum and beyond, where exact load requirements
are needed. Almost all sane amateur use would not be in that exact
load requirement category.

Plot the resistances of bulb sizes from 10 watts through 500 watts
and draw a model of that function. My expectation is that at around
the 150-200 watt range, it comes very close, or sufficiently close for
practical use, to be a good load for the average 50-75 ohm ham gear.

At HF, the inductance is negligible. Calculate the inductance of a
100 turn coil, 0.1 mm diameter, 15mm long, and you should see that
at HF that it is almost a null inductance. At 2M or above, it could
be significant, but for our load purposes, it is an HF device only.

> Or if you only care how good it is as a dummy load,
> just can take the lazy ham's (my) way and stick an SWR bridge in
> the line and measure it!

I did, and as the 4-400A runs through resonance, the swr dips to null,
the bulb reaches maximum brilliance, and all looks rather like on the
globar load. Practically, it is pretty good.

> Be advised that a light bulb sucks for anything that requires a
> quantitative measurement because of it's sensitivity to power.
> miker

Yes, it will not do for precise power quantitation, most of the time,
but one could calibrate a pyrometer against it and it should be
reasonably close, but not all that exact. Someone did that back

in the 30's for calibrating output powers, and it actually worked fairly well. See QST of that era. All it requires is a calibrated light meter of some sort, and in that era a selenium photocell was used with a galvanometer, if memory serves me correctly. I don't remember if a series resistance was used to make it a voltmeter. Standardize it against a run of AC powers for whichever bulb sizes you wanted to use, and it should work, reasonably well.

I have used clear silicone sealant with good success. People have issued warnings that it will corrode wires/copper clad board, but I have never had this happen!

The best thing about it is that it is easily removable. It can be peeled off.

Most NiCd systems charge the battery with a constant current. A solar panel behaves a lot like a constant-current source. So the two work very well together. If you use a solar panel which puts out a current of about the 1/10 the amp-hour capacity of the battery, you can connect it directly to the battery. (That is, use a 50 mA panel for a 500 ma-h battery, etc.) You can add a series diode to prevent a small discharge from taking place when the panel is dark. The panel should be able to provide enough voltage to furnish about 1.5 volts/cell. But you can also safely connect the panel to a battery with a lower voltage than the panel provides, since the panel will produce about the same current regardless of the battery voltage (up to the maximum voltage of the panel).

Hot-melt glue wasn't among the materials I tried in my experiments years ago. I'd be surprised if it's a very good dielectric, though.

You can probably get by with using any of a number of relatively poor dielectrics, like epoxy or standard RTV, if it contacts only a few turns. I was looking for something to weatherproof an inductor (because water between turns does horrible things to the Q), so was testing coils which had been completely covered with various materials. What I ended up using, by the way, was some butyl rubber stuff I had gotten surplus. It resembles "Coax seal", but I'm not positive they're the same. It did surprisingly well in my tests.

Hi Doug,

Holy cow Doug, you really do not have to fall all over yourself
apologizing,
for, what? To whom? The radio collars I am familiar with give the dog
an electrical
shock, which gets his attention. After a while, the shock is not
necessary,
just as in the use of electric fences, because the animal associates
crossing
a certain boundary as undesirable. This is the intende, positive,
result.
There is nothing 'offending' about the use of these training tools,
except perhaps
to some of the fringe "animal rights" crowd. They would have us all
eating
nothing but veggies (but wait! killing innocent living plants for
food..).
There is no axiom that says that one is entitled to go through life
"unoffended'. I certainly haven't and would never expect to.

>www.iinet.net.au/~richardh/VK6BRO.htm

Regarding temp stability of varicaps: we did a study of that
at 10 MHz at Hewlett-Packard for a crystal oscillator. They
run from a few hundred PPM/degree C to about a thousand, and
the tempco is typically a function of tuning voltage. We read
the various Motorola appl notes on temperature compensating
varicaps and tried to use their ideas to temperature compensate
varicaps. Turns out you basically can't do it if you're going
to be changing tuning voltage and the appl notes are simply
misleading. We ended up depending on the crystal oven to
ovenize the tuning diode. If you want to read the complete
paper on the oscillator (of which a small portion is devoted
to this subject) it is on my web site: <http://www.karlquist.com>

Regarding tuning range, with AM radio tuning diodes like the
MVAM109, you will surely be able to get at least 3:1 frequency
tuning range, since the broadcast band is 550-1700 kHz.
You might be able to get 4 or 5 to 1, but it is probably better
to break up the band into several segments with several oscillators.
We once got silly and built a VCO that could tune from 1 to 30 MHz
in one range using a tuning diode just to see what could be done,
but it wasn't a very good oscillator.

Hope that helps.

I have some 800W 50 ohm non-inductive flat pack resistors. They just need to be thermally bonded to a heatsink and run up to an appropriate connector with a short, straight length of copper braid. This works well even at VHF. If interested let me know!

it is important that the rotator will do at least 420 degrees, then it
is some problems using a potmeter without a geardrive

I made a CMOS counter to count the 64 pulses per round for the AR-22
rotator, but after some use it needed to be reset, the output from the
U/D-counter was fed to D/A-converter consisting of R-2R network and a
741 to drive an analogue instrument. Some sattv rotators have 3 pulses
per degree, 1080 pulser per 360 degrees, making miscount a smaller
problem, I am told that counting and conversion to degrees is easily
made using a PIC16C84 with 3 digit display, but I still like the
potmeter versions better

At least one gentleman has pointed out that the right sized bulb comes close enough to 50 ohms to be very useful. Network analyzer measurements would be useless, since the bulb's resistance changes by a factor of 10:1 or more as it heats to temperature.

Some time ago, ten or so years ago, a fairly new amateur asked me much the same question.
I answered him by suggesting that he put away his vhf radios and go back to operation hf for a little while. The when he got back to hf for a few months he could pull out his vhf radios but to put more emphasis on hf then vhf.
In my opinion, you can learn more about the 'essance' of amateur radio on hf than you can on vhf.

Hi Steve,

There wre some good articles about building HV capacitors in QST some times ago. Here are the references:

```
@ARTICLE{ jones:94,
AUTHOR = {B. Jones},
TITLE = "{A Home-Brew Loop Tuning Capacitor}",
JOURNAL = {QST},
YEAR = {1994},
pages = {30-32},
month = {November}}
```

```
@ARTICLE{ rusgrove:75,
AUTHOR = {J. Rusgrove},
TITLE = "{The Trombone Trimmer -- Build Your Own Variable Capacitor}",
JOURNAL = {QST},
YEAR = {1975},
pages = {22,23,34},
month = {November}}
```

If I were you then I would make sure that it is permitted to put
a constant DC voltage over these bipolar electrolytic caps,
because they are made for applications in which there is usually
no DC voltage component, particularly in loudspeaker crossover
filters. A constant DC might ruin your caps in short time !!

I'm not sure, but I thought I should warn you.
Take care,
Jeroen.

I would advise strongly against the use of hot-melt glue. I am not sure of this, but I don't think it is a very good dielectric at all. I used some once to steady the stub of a 70cm J-pole once. I don't remember the exact method I used, but I found that the J-pole performed fairly badly with the topmost support in place, and hot glue bridging the points. This is, of course, a high voltage point, but the difference in performance with and without the hot glue raised some questions in my mind about the quality of the stuff for dielectric purposes. Of course, if you are talking lower frequencies and lower voltages, it would not be such an issue, but I would recommend trying something else.

I have to agree with the other posters - absolutely buy a copy of _The Art of Electronics_ by Horowitz and Hill.
There's a student manual that comes along with _Art_ as well, which I've found to be helpful in structuring my study, which is necessarily fragmented as it's squeezed into the cracks around my job and family life.

Intro to RF Design by Hayward has been useful to me also.

Another suggestion that people have not made: read through a number of different texts, perhaps at a library, to find one whose style appeals and is clear to you; everyone's brain works differently and I've found huge differences in comprehensibility from author to author. Find out what fits your learning/comprehension style.

Good luck and 73,

Joe, you are a little too new.....(:+}}.... Go back aways to something
like the TBK manual, or the TCK manual, or something like that. I will
see if I can lay hands on my TBK manual and quote therefrom.

The standard glowbar dummies came in after WWII, in the ``modern era''.

But, I still am quite happy using a lamp load on my SRT-14, if you remenber
those. Most had been phased out by 79, but a few may have been around
still. Mine has overhaul dates of 69, as the last thing I can find on it.

Is that latter small roller for vhf? If its got a lot of turns and smaller gauge wire, I bet 2kw would fry it. I have one slightly larger, and by my calculations, it would be good for a few hundred watts, maybe even 500, but in a resonant circuit transferring 2KW, theres quite a bit of current. I doubt the larger one would be good for more than 1.5 KW of rf.

He is probably an old timer. By 1979, most millitary technicians were chassis changers, because the equipment became too complex for many field repairs, so depot and OEM repair became the norm. There was a lot of requirements for self testing features in most equipment. I'm not moaning about it, it just became neccesary, and made sense because electronics became more reliable, and cheaper.

By the way, I'm the one who started all this light bulb stuff. I reccomended a 100w bulb for the 100w transmitter, but now that my dim memory is coming back, I remember that the last time I used the 100 w bulbs as dummy loads, it was for a single tube 6146, so it probably had 40 or 50 ish watts out, and that pretty much falls in line with everyone elses experience. I do remember that I was impressed with how well it worked at hf. I realized that there is a short interval at first power where the bulb would present a very low impedance, and I still dont know how solid state would react. If the self protect circuits didnt shut the output off completely, I guess it would be ok, and still work fine. Might just depend on the design itself.

I never used bulbs routinely. They have to be replaced and so forth. But they do make for a cheap and quick dummy when you need it. I remember wireing multiples up to get a quick and cheap load, but I dont remember the details of that experiment.

I'm not real clear here. What do you mean by the inputs and outputs?...
anyway, if the beam wont focus without an input signal, it wouldnt be a
capacitor problem, just not the right dc voltages on the electrodes of
the crt. You might have to modify your circuit to get a wider range of
focus circuit voltages. Where is the 3300 mfd at. It seems awfull high
for a crt circuit (maybe 3300 pf?).
Try to go back to basics, and make sure you have a zero input signal.
Check it all the way up to the deflection plates (theyll be equal dc
voltages if differential). Defeat the sweep circuit so there is no
horizontal sweep on the crt. Then work with the dc beam voltages till
you can get a dot. Take care to keep the intensity low so you dont burn
the crt face, and be carefull of the high voltage so you dont get
shocked. Then reintroduce the horizontal sweep and work toward getting a
thin line thats just slightly shorter than the width of the crt.
Finally, reintroduce the vertical signal.
I hope some of this is helpfull, but I didnt totally understand some of
your post.

True. But you generally get the highest Q by evenly spacing the turns around the core (and, better yet, choosing a core size that one layer just covers). This might not be practical at 6 meters, though.

> Here's another topic for discussion: when do I want to paint a toroid with
> Q-dope, and when should I leave it bare (if ever)?

In my opinion, you should always leave it bare, unless you have a good reason to coat it. The dielectric between the turns will increase the inter-turn capacitance and introduce a potential source of frequency drift. (Come to think of it, though, the tempco of styrene capacitors is in the opposite direction from that of typical good inductors, so you might get lucky and the coil dope might actually reduce the inductor tempco -- or it might overwhelm the inductor's tempco and make it drift in the other direction. I prefer to get things to work by design rather than luck, but each to his own.)

If the focus knob goes to one end before you reach proper focus then
then chain of resistors each side of focus pot is wrong.

Thanks, I've checked the horizontal input and vertical input seem
to be working with dc voltage applied even though I have a .01
mfd cap in the circuit. I have a square dot on the screen. I can
get it to focus when I move the focus from pin 5 to pin 7 of the
crt, but I haven't gotten the straight line. I built it for
monitoring AM. Do you think this will be ok for monitoring a CW
transmitter? Or AM transmitter?

My VFO tunes from 6MHz to around 12MHz, and I'm then mixing it up to 6 meters with an xtal osc in the 43 MHz neighborhood. I know, I know, this tunes beyond the ends of the 6M band. I'm going to use a frequency counter to ensure I don't transmit outside the band.

Re: even spacing: I thought that one wanted to leave a certain angle between the ends of the winding, something like 30 degrees, to minimize interturn capacitance? Am I mis-remembering?

I agree that things should work by design rather than luck, but
that doesn't mean one should discount the value of serendipity. If
application of coil dope reliably introduces a compensating property,
that's not luck, that's science, all one has to do is adequately
characterize the influence (gain an understanding of how core size,
number of turns, turn spacing, wire size, thickness of dope and
other variables) relate to the effect. I'd hate for someone
to just blindly repeat "coil-dope cancels out temperature drift",
but, on the other hand, this might be a very useful technology
(if it works at all ;-)).

On a side note, I'd wager that most amateurs probably lack the
equipment and/or techniques to even begin this kind of experiment,
and that's really too bad. It means they're dependent on luck
all of the time, not a good thing.

Hi Don
Have you ever looked inside a large tuner? You know the ones that
handle
2KW+? Well the big one is about 3 times the size of those. The little
one is also quite hefty. The size of the wire is #12. I really doubt
that whatever we use will do any harm to either of these. My suggestion
would be try loading into a more resonant antenna. I also have no idea
how you came up with the calculations for VHF? I used the small one in
a Thunderbolt Amp that worked excellent and was basically the same size
as the original but much higher quality. I think this proves that the if
the small one can handle two 4-400s on HF then the big one should handle
far greater power levels. What do you think? If you have any further
questions please contact me through direct e-mail. 73 Chris

I dont know about vhf rollers, never saw one, but I wondered if they
might exist. I got the determination for power handling for the inductor
I have from the AARL handbook. I did have a Johnson Killowatt amplifier
one time, and it had a hell of a lot larger inductor than what you say
will work at 2kw. I have also fried a few inductors that were larger
than your 2KW+ Inductors that are 4" by 2". you never did give the wire
gauge, which is the most important parameter. Yes, I have seen some
rather shitty commercial tuners, and I have one rated at 300 watts. It
works fine, as long as the load is close to being matched. Otherwise,
its good for about 75 to 100 watts. If the load isnt nearly matched, it
will arc occaisonally anyway. I realize you cant get back here too
often, so I sent you a copy as you requested.

Actually non-polar electrolytic capacitors are designed for circuitry where the polarity might _occasionally_ be switched. They handle DC just fine when kept within their ratings. Unlike regular electrolytic capacitors, however, the DC field does not keep the anodic film "formed". Their application in AC circuits is not considered good design, especially in circuits like crossovers. They are used in these circuits only for their small size and low cost.

Hot melt adhesives can be of several types. The polyvinyl acetate types have moderately high dielectric losses but the amorphous polypropylene type is excellent. Something easy to use that has excellent dielectric properties is ordinary paraffin wax like that used in home canning and in candles.

The CW that he is hearing is not really CW. The NDBs (non directional beacon) transmitters identify with Morse code. It is amplitude modulated on top of the carrier. Occasionally you can turn an AM BCB radio down to the low end and hear the beacons if they are close by.

By the way, these things are scheduled to be phased out in another 5 or 10 years. Any chance of getting a ham band in this area?

Just below the AM broadcast band, at 510-535 kHz, are air radionavigation beacons. In the U.S., most of the spectrum from 20 kHz up to the AM band is allocated to maritime mobile or aeronautical radionavigation. This is generally true of the rest of the world, too, except that Region 1 (which includes Europe) uses 148.5 to 255 or 283.5 kHz for additional AM broadcasting.

OK, I went digging back into ancient lore, and found John Nagle's paper.
Since I made the statement on such use, I figured I should put the
guildern de realme where the ol' choppers reside.....(:+}}...

It was in CQ, January, 1951, pp. 30, 31, 56. John was an electrical
(electronics? RF?) engineer in the Wash., D.C., area and passed away
about 5 years back. Anyway, his data, Figures 4 and 5, are of most
interest. There he shows the change in resistance vs current for
standard lamps of sizes 25, 40, 60, 100, 200, 300 watts. Of particular
interest is the data for the 200 watt bulb, at a 1 amp current (that
approximates a normal 100 watt rig, at 50% efficiency). The resistance
of the bulb at that current level is almost exactly 52 ohms. At a
current of 1.4 amps, it approximates 72 ohms. The 100 watt bulb
has a resistance of 50 ohms at about 1/3 amp current. The 60 watt
bulb has a resistance of 50 ohms at about 1/10 amp current.
For a 300 ohm load, the 40 watt bulb would be good at around 1/4 amp
current. Earlier I mentioned that the Navy had used 500 watt Mazda
bulbs as loads for the 1kw HF sets (typically a TBK or such).
If one follows the line of data in Nagle's Figure 5 with a theoretical
line for a 500 watt bulb, it would tend to suggest that a 500 watt
bulb would present a 50 ohm load at around 5-10 amps current, which
is pretty close to actual currents in those large Navy transmitters.
Thus the suggestion of the use of a 500w Mazda lamp as an RF dummy
load, by the Navy, in the 30's-50's era, for 1KW sets is quite well
founded in theory and practice.

Interestingly, the 200w bulb is what I have been using since Hector
was a pup. It is entirely in line with Nagle's data.

Two other references of note, for using lamps as resistors in ham
circuits, are F. Hamburger, Jr., ``The incandescent Lamp as a Resistor'',

QST, July, 1934, p. 31, and Redgrave, ``The Light-Bulb Resistor'', QST, March, 1934. Mr. Hamburger (interesting name) was an instructor at Johns Hopkins University, School of Engineering. His article provides data on the voltage drop/current ratings of standard lamps as might be used in the making of resistors for power supplies and such (lamps can make great voltage regulators and dividers for HV power supplies where large dissipation loads are desired).

There are a couple of other references that I have run across, but I was unable to find those on short notice.

Anyway, in the hope that some folks might find it at all useful, I pass in on to the crewe.....

5595. Headset mic: tone questions!

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-10 00:00:00 UTC
From: gdfthr768@aol.com
Message-ID: <19981209235729.00719.00000254@ng-cb1.aol.com>
Source record: 76038

I have built a cheap (something like $6 in parts) headset mic for my rig, works with a footswitch PTT, and followed the ARRL Book for '97 to get it right. It works exactly as it should, but the tone of the electret element leaves a lot to be desired.
Is there a way to take some of the hiss/high-end out of my tx audio without buying a new mic element? Perhaps by adding some components inline, etc.? I already put a baffling foam around it, but it didn't help a bit... <uurgh!>
Curious, and please send any replies to the group, thanks! :-)
Mike in MO.

Hi! I do have the tubes listed below for sale:

4x 4-400A(pull from working equip.) $40.00 each
1x 280(used) $25.00
2x 232(used,tested) $8.00 each
1x 33(pull) $3.00
1x UX-112(used) $20.00
1x UX226(used) $20.00
2x UX171A(used) $20.00 each
3x 8791(pull,tested) $100.00 each (datas available)
2x 6550(few hours used,tested,1ST & 1GT) $50.00/pair
2x 5881 N.I.B. $40.00/pair
2x 5881(used few hours only,tested) $25.00/pair
1x 2050A(new,Phillips,usa) $10.00
2x 2050A(pull,tested) $5.00/each
2x 8417 N.I.B $50.00/pair
1x 931A N.I.B RCA $20.00
3x 7360 N.I.B. GE usa $30.00 each
3x 6267 N.I.B GE $18.00 each
2x 6267(used,tested) $8.00 each
1x KT66 GEC n.i.b. $70.00
1x 272A Western Elect. NEW $60.00

All pulled tubes are from working equipment,unless mentionned
as new(NIB),if you are interested in some of them,
please email me for more informations.Amounts in U.S. funds.
Thank

Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I have two roller inductors. Both Porcelain. One is a very large unit capable of handling very high power. The roller is 9.5" long and 3.5" wide, it has about 80 turns of wire. The contact rides on a glass rod. Very smooth turning, and in excellent condition. It will handle from broadcast band all the way up past 30MHz. This would be great for a large amp or a large antenna tuner. $175 shipped.
The second Roller is much smaller but equally the same quality. The roller measures 4" long by 2" wide with 24 turns of wire. This would be great for a smaller tuner or transmitter up to a 2KW+. $75. Both these roller inductors are in excellent shape. I just changed my mind on the project I was working on. 73 Chris VE3NGW/W4 Florida

Richard: Here's a much less scientific response. I think the Varicaps get generally bad reviews in the ham HB litereature. I never used them until I picked up a version of the Doug DeMaw Barebones superhet built by another ham. This fellow used varicaps in the local oscillator (9Mhz). He used a DC-DC convertor to let the give the varicaps more range than he would have got with only 12 volts. (I think the Q was higher at higher voltages also.) I simplified it and just run the varicaps through a 10 K pot from the 12 volt supply. After a few minutes they stabilize (sort of like using tubes!). I can cover 14.0-14.2 Mhz. Kind of a neat circuit.

5604. Re: Headset mic: tone questions!

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-10 00:00:00 UTC
From: Roland Burgan <rburgan@up.net>
Message-ID: <366FD53A.DC8054B9@up.net>
Source record: 76047

You may be getting RF feedback into the audiio. Make sure
everything is well shielded, and you may try a bypass
cap across the element, for RF, about 220pf, and bypass the
DC at the mike jack used to drive the Electret element.

Bob,
When were you in the Navy or are you going on someone else's memory.
Not that I am an all out authority on what the Navy used. As an ex-Electronics

Technician in the Navy ('79-'89) I never used a lamp for a dummy load when
working on an HF transmitter. We had 50 ohm oil filled dummy loads for 1kw
and 5kw. Yes, we had 5kw UHF xmitters on the ships for a while. Thought
you would like to know.

Joe

Hi Joe, Yes, 73 Magazine is still published by Wayne Green. It is however, just a skeleton of it's former self. I've been a subscriber since 1969, and this last few years has seen the mag really fall off in quality of articles. I'm also a bit miffed about the delivery times. I used to get the monthly edition during the first week of that month. I received November's edition on Friday, December 4th. Even after many phone calls, I have got no resolution from 73. It's too bad, cuz they once had a lovely magazine, some editions ran upwards of 250 pages. I still use them as a reference library when homebrewing. They do not have a web site, and at one time used a Compuserve address for e-mail. I'm not sure if it is still valid or not. 73 es Merry X-mas de VE6INM (Glenn)

Hello, I've built a monitor with a circuit from 73 ARRL book. It works, except the focus won't really focus. Does anyone have any idea what may be wrong? I used .01 MFD caps for input and ground connections. The schemetic showed 3300mfd. Could this be the problem? The ugly system seems to work, but waiting for something to monitor with specifically. All I've connected so far is a code oscillator circuit and got a voltage rise and flicker any suggestions? Thanks.

I'd like to say thanks to everyone for the many useful suggestions and helpful responses. Perhaps we'll QSO on 6M someday, if I get a rig built in time for the sunspot peak!

Another thing that I'd like to see is a neat way of securing the wires that come off the toroid.

In some commercially assembled boards I've seen little plastic holders that grab the toroid and provide little mounting posts for the toroid wires. Anyone know of a source for such things that would fit the size 37 and 50 cores?

Some folks have suggested that it doesn't much matter what you use if you glue the bare part of the toroid to the board, which seems eminently sensible at least for my application, which doesn't require coating or waterproofing the coil.

Here's another topic for discussion: when do I want to paint a toroid with Q-dope, and when should I leave it bare (if ever)?

> about 50 deg. C.

For the box, I'd suggest that hi temp ceramic cloth. There are diff.
mfg.s
that make ceramic cloth and other ceramic materials, sheets, etc.
Also
diff. made from silica, and other elements. They use the ceramic
tiles on
the bottom of the shuttle, light wt. and takes alot of heat. There
some
home made kilns where they wrap the inside of a small chamber, like a
30
gal metal garbage can w/ the ceramic cloth, then take the temp up to
firing
temp., like 2000 or 3000 deg. F , procelian temp. Multi-zone ovens
use the
ceramic brick as a lining.

I found a few sources in Design News, Ceramic, Machineable, Ceramic
Products
Inc, precision high tech ceramics, NJ, 1-800-828-6344. I got alot of
info
from looking ar Chemistry related suppliers. I remember a company in
New
York that sells the ceramic cloth, I can get the address if you want.

Source record: 75979

I honestly don't know how much effect a 30 degree gap in the winding would have. The reason that full (or near full) coverage (unless turns are very sparse) gives the best Q is that the coupling between turns is maximum, giving the most inductance for a given amount of wire. It does, though, like you say, increase the shunt C, which will lower the Q. It seems reasonable that the optimum Q would occur with some gap. I'd guess that the optimum gap would depend on the core permeability and other factors, but 30 degrees might well be a good rule of thumb.

I haven't done Q measurements with a gap this size, and will try to find some time to make a few. If someone else has good measurements, please post them.

The Micrometals _Q Curves_ supplement shows an example of 90 and 100 turns on a single layer on the same type core (type 2 material), with 100 apparently completely filling one layer. The maximum Q is higher with 90 turns than with 100 (although the 100-turn inductor Q is slightly higher at lower frequencies). Unfortunately, they don't show how the turns on the 90-turn inductor were distributed. The difference in any case is small, with the maximum Q being 248 for the 100-turn inductor and 244 for the 90-turn one.

Until I get more information, I'll qualify my statement to say that the maximum Q occurs when a core is _nearly_ filled with a single layer.

From: Don <bjmcpher@usit.net>
Message-ID: <3670CA05.A0BB0879@usit.net>
Source record: 75981

Has anyone seen any data or general guidelines for how much voltage a heat sink insulator can safely hold off? I have an assortment here, and there are several types: Some grey colored ones that are like rubber, very flexible. Some yellow ones that seem like a plastic film, also, some clear ones that might be the same material. And of course, some of the old mica types.

Don

ExpressPCB makes prototyping with PC boards easy and
inexpensive using our free layout editor.

Here is how it works:
1) Download our PCB layout editor for Win95.

2) Using this very easy to learn CAD software, design
your two layer board with plated-through holes.

3) Order your custom PC boards directly from the layout
edit using the "Order Boards Via The Internet" command.

4) Within 2 or 3 business days, an overnight courier
delivers your boards, often for under $100.

For all the details, check out: http://www.expresspcb.com

Don,
My first xcvr's that I took care of were AN/SRC-20's. No solid state electronics there. All tubes, adjusted the xmit and rcvr by bending tabs in the VFO and xmitter with orangewood sticks. Lots of alignment for UHF. I had eight of these and had a rotation of aligning one a day and working my way through them about every week to keep the power constant across the bands. The HF xmitters were almost as bad. R-1051 receivers, R-390's receivers, T-827 exciters, AM-3927 HF Amps. Lots of tubes and some solid state in those. I didn't get to work on any new solid state xmitters until I started working on SATCOM equipment. AN/WSC-3's.
Still nice to hear old salts talk. I have gotten lots of good info from this group and enjoy hearing other experience with ham gear. I still prefer my ICOM over any HF gear that I had in the navy.

5621. WANTED: MC3448A GPIB Bus Transceiver IC's

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-11 00:00:00 UTC
From: owens@ale.atd.ucar.edu
Message-ID: <74re84$o15$1@ncar.ucar.edu>
Source record: 75985

I need several of these Motorola IC's to repair the GPIB board in
a HP5335A counter. The HP part number for the IC is: 1820-2058. Or,
would like to find a GPIB pc board for the HP5335A counter in good
working condition. It is the A7 pc board: " HP-IB Logic Assembly"

If someone can offer a part number for a suitable substitute that is
a currently available integrated circuit-that would be super!

Thanks,Chip Owens, NW0O, Boulder, CO

What I've done in the past is to first test the torroid in the completed VFO to make sure that the windings are correct in number and distribution around the torroid. When I'm satisfied that all is correct, I cover the bottom 3/4 of the torroid (assuming vertical mounting) with nail polish (I like bright red.). After it's dry I epoxy the torroid to the board using just one big drop of the mixed goop. Finally, after all is dry, I do a last retest of the circuit, moving the last uncovered windings to tweak the value. Once that is done you can either coat the last windings with more nail polish, or leave them uncoated for later adjustment.

5623. WANTED: Ideas for oven & controller ckt.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-11 00:00:00 UTC
From: owens@ale.atd.ucar.edu
Message-ID: <74rfiq$q7u$1@ncar.ucar.edu>
Source record: 75987

The assembly consists of 2 hybrids and a pair of crystal filters. There are several ferrite core inductors that I want to maintain at a constant temperature. Powdered iron cores, or air core inductors won't work in this application, hence the ferrites (and their poor tempco).The size of this assembly is approx. 4" X 6" X 1.25". The assembly is currently enclosed in a shield box made from sheet brass with a pc board bottom. So a heater could be attached directly to the bottom of the box. Insulation and a larger box around the first one seems likely-not limited by size at this point.

Main considerations are stable temperature and *not* introducing any extra rf noise into the system.

An extension of this idea for a future project is to build a small chamber to do temperature testing of circuits. Here I am thinking of maybe a shoebox sized oven to test performance at elevated temperature, or to maintain a known & stable operating temperature to test oscillator drift. In this case I'd like to be able to set the oven temp.over a range of temps from 20 deg C to about 50 deg. C.

Any ideas or suggestions cheerfully accepted.

Thanks, Chip Owens, NW0O

Source record: 75988

"When using insulators, care must be taken to keep the mating surfaces clean. Small particles of foreign matter can puncture the insulation, rendering it useless or seriously lowering the dielectric strength. In addition, particularly when voltages higher than 300 V are encountered, problems with creepage may occur. Dust and other foreign material can shorten creepage distances significantly; so having a clean assembly area is important. Surface roughness and humidity also lower insulation resistance. Use of thermal grease usually raises the withstand voltage of the insulation system but excess must be removed to avoid collecting dust. Because of these factors, which are not amenable to analysis, hi-pot testing should be done on prototypes and a large margin of safety employed."

-- Motorola Application note AN1040, "Mounting Considerations for Power Semiconductors"

I'd consider this information in addition to whatever manufacturer's specifications you might find.

How does one tell the difference?

I just tested a general-purpose glue stick in the microwave oven and the losses at 2.45GHz were very low (lower than the glass that was used to hold it upright).

Needless to say, there was no information on the pack. If it helps you to identify the material, Barry, it was very similar to polyethylene in its translucent color and flexibility, but had a slightly sticky feel at room temperature rather than the waxy feel of PE. It is low-melting and rapidly becomes much more sticky at higher temperatures; it also pulls out very easily into fine filaments.

It seems to work well for general-purpose waterproofing of HF antennas, although that is not a very severe test of RF losses.

Am I right in assuming that a laser printer is essential in this method,
please?

I have tried with my Canon BJ10 Bubblejet, using this exact paper, but have
had no success at all. Since a bubblejet uses a hot spray process I would have
thought the ink would respond to reheating. It doesn't !

Has anyone had success with any other kind of printer ?

Tom.

Thanks, Roy

Another fellow emailed me some data. It seems that the micas are around 300V, and the grey "silpad" is about 150V. He didnt have data on the clear and yellow plastic insulators. I had never thought about the cleanliness aspect, but it sure makes sense, particularly if some fine conductive fragments were present like filings or the like. I'm right on the limit for the mica insulators, so I may just have to play it safe and isolate the whole heatsink. I hate working with HV (unless its tubes :)). If you make the slightest mistake, its all destroyed, and you start over! With tubes, sometimes you get a second chance if youre quick on the main switch.

Hi, Joseph.

Some of those old boatanchors were really bad. I had an Icom, but I sold it about 10 yrs ago. It was really nice, but I made the mistake of getting the real tiny one, and I never could get used to those tiny knobs, what with my clumsy big hands! The only rig I have these days is an ancient collins S line, and it hasnt been to bad about having to be realligned. Of course, at HF, you can get away with a lot more. I once worked on a fire control radar (all tubes), and That thing wouldnt stay alligned more than a day either. I never tried a light bulb on the microwave output :)

Chris OM,

Do not be misled by advertising claims of tuners being "2KW" or such,
and
then looking inside to see what size components they are using. Those
claims do not usually represent reality, especially at matching
extremes.
Most of the components used in commercially made ham radio tuners I have
seen are much smaller than would be indicated by a rigorous design for
those power levels.

You might try looking for some beryllium oxide insulators. Good heat
conductivity, but I think they can withstand much higher voltages
because they're considerably thicker.

The processes are very different. Laser printers use little plastic
powder particles, which are melted onto the paper. Heat can cause them
to transfer to other things, like copper PC board. Bubblejet printers
use heat to boil water, expelling a blob of ink. But the ink is water-
based and soaks into the paper. There are no plastic toner particles
to transfer onto the copper PC board.

New Amateur Radio Search Engine online......

There is now a dedicated Amateur Radio Search Engine for amateur operaters. It is located at http://www.surfsouth.com/~wharrell/fest

This is the Sunbelt Hamfest site and has the link to the new search engine. As the database grows it will help Amateur Operators locate Amateur relate sites easier.

Sell that surplus gear during the holidays and have more for Christmas. Send your listing to wharrell@surfsouth.com and put in Subject: Hamfest Listing

We look forward to your emails and invite you to post your page in the Search Engine.

The hamfest boneyard listing is free.

Chip..... many moons ago, when laboratory gas chromatography was an art form,
I used to build my own chromatographs. For the ovens, I borrowed an old
Radio trick. It worked very well. It amounted to making a double box out
of 1/4 inch aluminum sheet, sized to suit. Mine were 1 foot square, with
a door on one side for access to the internals. Then take a small porcelain
socket, and mount inside. Put a suitable standard lamp in the socket.
Power it with a suitable ac voltage to give you the required heat input
to balance the heat loss at whatever temperature you need to run. Mine
used nothing more exotic than a small variac to the 110 AC line via a
regulating transformer. It held the temperature on the GC column to
well within 0.1 degree C, more than adequate for our use. I basically
borrowed that trick from the old RMCA marine receivers which used heating
resistors in the filament string to keep the receiver cabinet warm under
all conditions, at sea. You could probably use a 50-250 ohm resistor,
but they don't radiate the heat as uniformly as a plain ordinary lamp.

For a box your size, put half a dozen resistors in series and mount them
all around the box maybe. Put the box in pea gravel around the resistors
to make the thermal flow as uniform as possible. If your temperatures
to heat to are between ambient+10C to 100C or so, it will work fine,

and is readily calibratable. Ambient to ambient+10C is a little more difficult to calibrate, unless you have a well-insulated box with little heat loss. The idea is to allow just sufficient heat loss to be readily controllable on the heating elements so that they balance at whatever temperature you want to run, for whatever size bulb you want to use.

Ordinary AC at 60 hz should not introduce noise into your system. The old chromatographs that I used had Cary electrometers on them that would measure an electron flow of 10exp-15 amps current across a flame detector. Electrical noise from the variac controlled bulb was nil. That would be more than satisfactory for ham radio use. If you stay away from mechanical or electrical contactor controllers, the noise will be null. Electronic controllers can be noisy, and easily blown.

For a temperature range of 20-50C, a 25 watt or maybe a 40 watt lamp or equivalent resistance, should do nicely, on a variac.

Good luck!

Bob/NA4G

p.s. Another fine ham use for those silly lamp bulbs.....(:+}}.....

Hello
I also was looking for a website for 73 magazine. The other day I read and I can't for the life of me remember where. That Wayne Green Inc. filed for bankruptcy. The magazine is in his wifes name and is still being published but on a lesser scale than before. I was sad and surprised at the same time. Wayne was a big one for talking about making money with the technology of electronics form ham radio. It's seems strange that after all that 73 doesn't have a web site even in light of the money problems. Sites aren't that expensive. They don't even have a email that I could find. I used to enjoy reading the editorial page because even if you didn't agree with Wayne he still had some good points.

Well several responses have been offered... but I'd like to add a historic note:

500KHZ used to be the international maritime distress frequency, many a ship sent out a CW SOS on 500KHZ (Hasn't everybody seen "Titanic";). I had the priviledge of spending many hours "guarding" the 500KHZ distress frequency during my time in the U.S. Coast Guard, as well as being the operator who responded to several SOS's (an event which will definately get your heart racing). The frequencies slightly above and below were used to pass commercial traffic as well as come freq's that were used to broadcast maritime weather and other warnings. Alas, this was all CW and these frequencies have been abandoned for that use (I don't know what the official FCC/International use for 500KHZ is these days)....

Those were the days when ship to shore communications were the perview of professionals... (boy could some of those guys pound a key!)... now all you need is a celluar phone....

You're right on about the beryllium oxide insulators. Be careful not to breathe any dust from a broken one -- it can be toxic if inhaled. They should be easy to identify, being white ceramic. I've never heard of anyone making an insulator from aluminum oxide or any other of the poorly thermally conductive ceramics, so don't think there's anything you could confuse it with. Anyone who has seen transistor insulators made from any other kind of ceramic can correct me.

Hello--
I've seen a pink-colored ceramic used in transistor headers (e.g., the
2N2876) and in heatsink insulators, and I dimly recall that the pink
color denotes beryllium oxide, too. Can anyone confirm this?

73,

Yes, contact is sufficient! It is not something to be fooled around with --
even in military/industrial applications extreme caution is exercised
during handling.

I thought that the silicon rubber insulators were far better than the mica ones. These voltages seem rather low to me. I suppose cleanliness does enter into the equation, but has anyone made REAL tests? Cliff K7RR/W6HDO

I was thinking about a ham in another newsgroup or here, He thought about buying copper stripping foil and placeing it on cardboard, but I was thinking about using a plastic sheet. The foil can be bought at a hobby center and then cut and peeled to stick to the plastic sheet in anyway imaginable. Parts can then be soldered to the copper.

>there are several types: Some grey colored ones that are like rubber,
>very flexible. Some yellow ones that seem like a plastic film, also,
>some clear ones that might be the same material. And of course, some of
>the old mica types.

The gray ones are usually silicone or fiberglass impregnated silicone. Their voltage rating is not very high. Berquist is the company generally associated with these. These have the worst loss tangent of the group if the insulator is going to be used at high frequencies. Their thermal conductivity is not the best either but they avoid the mess of using silicone grease.

The yellow (or brownish orange) ones are probably Kapton (DuPont's version of polyimide polymer). They are quite strong physically, rated for high temperatures, and have good electrical properties through the low microwave region

The old standby, ruby mica, is naturally rated for the highest temperatures (well above the temperature that the typical semiconductor fails). If the surface is not damaged, it likely has the highest voltage rating. The RF dielectric properties are excellent.

With the last two types, you will need silicone grease to insure a good thermal contact. As Roy, W7EL, pointed out, you will need to insure the mating surfaces are very clean and very flat. If the semiconductor device will be at high voltage with respect to the normally grounded heatsink, consider using the Nylon insulating covers for the device. These generally snap on and provide lots of protection.

Beryllium oxide insulators are available at an extremely high cost. They are an excellent electrical insulator with a thermal conductivity greater than aluminum. BUT, if broken, they are EXTREMELY TOXIC. If the dust is breathed, ingested, or gets into a cut on the skin you can expect no end of health problems. Beryllium oxide is probably as good as mica in its RF properties.

Aluminum oxide is normally not used as a heatsink insulator because it has such poor thermal conductivity. However, anodized aluminum IS used. In this case the oxide coating is so thin that its thermal properties are not too important. These are only useful at low voltages.

Beryllium oxide is normally white. I have never seen it in pink, although it may have been produced that way for some special application. Many

electrical insulators made by Heany Ceramics are pink. In fact, this is their trademark color. I think most of these are Alsimag ceramics though.

Boron nitride is now being used for a thermal conductor / electrical insulator. I do not know if it is commercially available for heatsink use.

>Thanks for reminding us that sometimes we don't need high technology!

Ian and Roy (and others),

Most of the white hot-melt adhesive sticks for home use are the amorphous (atactic) polypropylene variety. As Ian noted, they are usually translucent white and waxy feeling. The "stickiness" is obtained by the addition of chemical "tackfiers". Once molten, the polypropylene become fairly tacky by itself, but additions are generally made to improve its sticking properties. Other things like fillers and antioxidants like Vitamin E are also added. My former employer, Eastman Chemical Company, was one of the major producers until they sold the business to H. B. Fuller several years ago. Their big competitor, Huntsman, is still in the business.

[Originally amorphous polypropylene was a waste material when the desired product was isotactic polypropylene (isotactic = all methyl groups are on

the same side of the polymer chain, atactic = randomly distributed methyl groups). Once good uses were found for it, Eastman "mined" large quantities of it from a landfill where it was previously disposed. Today the trend is for block polymers where portions of the chain are isotactic (hard and crystalline) and adjoining portions are atactic (rubbery and soft). The result is like a fiber reinforced material - the hard chains are held together within a softer material to make a strong, but tough, composite.]

I had previously mentioned the polyvinyl acetates and polyvinyl alcohols that were also used as hot melt adhesives. These tend to be found in industrial applications like corrugated box construction. While not a hard and fast rule, they tend to be tan or brown. These have poor electrical properties not because they are vinyls (polyethylene and polypropylene are technically vinyl polymers). It is because there are highly polar groups attached to the vinyl backbone. In PVC, these are chlorine atoms. In polyvinyl alcohol, PVOH, the polar groups are hydroxyls.

Paraffin wax, which I had mentioned earlier, is electrically similar to polyethylene but with a much shorter polymer chain. It is a great material for potting electrical circuits because it has low losses, is moisture resistant, and can usually be removed readily with a heat gun. Just be careful of its flammability.

I used to be a big fan of 73 Magazine, but the endless tirades of an
increasingly
disconnected-from-reality Wayne Green, the declining quality of the
articles, and
the chronic delivery problems drove me away years ago.

One would think that if he was serious about delivering state-of-the-art
information,
and that he really could make money as readily as he bragged, he would give
the
magazine away over the Internet and sell some advertising on the web page
to
cover the small cost of maintaining the page and reimbursing folks for
articles.

Oh well, when it is gone, we'll still live without 73 Magazine ... DavidC

You can use your bubblejet to print out the pattern then
photcopy the image onto the special paper, later.

The laser and copier use a powdered plastic which is fused
by a heat roller onto the paper. Ironing the image onto
copper merely welds that image to the copperclad. Getting
the unwanted paper off and leaving the image behind is the
tricky bit! :-(

Source record: 75916

I haven't seen a new issue of 73 here for at least a month, and I think longer. I thought for sure it was dead, especially since someone made some comment in rec.radio.shortwave a while back. But in recent years 73 has not had a reliable delivery date, and at least once before I thought 73 had died.

It hasn't been in great shape, shrinking in size and the content lacking and numerous errors (that at least got corrections), With those signs, it's easy to assume a late magazine means it's died. I'm still up in the air about whether it still lives or not, not having seen a concrete answer.

Wayne has always been successful at starting magazines, ones that seem to have good readership, but he sure hasn't been all that successful at keeping the magazines. When he started Byte in 1975, he put it in his ex-wife's name because he was having problems with the IRS at the time, and a few months after the magazine started, she and the editor Carl Helmers grabbed it out from under Wayne. I've never heard a full story about that, but I always think about Robert Heinlein's "Door Into Summer" which had a similar scenario, and which Carl Helmers mentioned as a favourite book.

Then he started Kilobaud, and eventually a bunch of computer-specific magazines, some more successful than others. When he sold them (and apparently he made a lot of money from the sale) 73 went with it. That period in the mid-eighties would seem to be the beginning of the fall of 73, since Wayne was not directly connected with running it, and eventually stopped even writing the editorial.

He went off and started other magazines, including his music CD magazine, I can't remember the name. At some point he got 73 back, mainly because the computer publisher that had bought it with the computer magazines did not want it. But a lot of damage had been done; I sure started losing interest in 73 when he wasn't connected with it.

He eventually sold the music magazine, I can't remember if it was before or after he got 73 back. Again he got a lot of money for it. Interestingly, all of the computer magazines have disappeared (some years ago, and Byte faded out in the early summer), and I think the CD magazine eventually faded out too.

He starteda cold fusion magazine a few years ago, and perhaps one or two other niche magazines. At one point when 73 wasn't looking so good (and I can't remember exactly when) he mentioned that he'd had problems with it and his CD company, something to do with choosing the wrong people to run things. I believe he went bankrupt then, but 73 was under a different

company so it survived. This was maybe two years ago.

In recent years 73 has been a fairly shoestring operation. I can't place the date, but there was a period when it started looking different and very noticeable errors started appearing, undoubtedly becuase the staff weren't hams. I think this was the period when his newsprint magazine meant for new hams folded into 73.

I have a fairly complete set of 73 magazine, starting from when I first discovered it in September of 1972 (a few months after I was licensed, and two months before the monster November 1972 issue, which curiously had an article about building a computer), and going back before then because I picked up back issues. I missed a few, when I wasn't feeling so great or I didn't buy the magazine before the new issue arrived. But in recent years I've missed more than I've bought; it arrives at the newsstand, I look it over, and there's nothing much there. A really sad thing. The issues I do buy seem to be more from habit than because there's something I really want. Admittedly, over the years the articles in all the ham magazines do tend to repeat, and nothing is as new as it once was.

I don't know where this leaves the magazine. Most of the above comments are from my watching the magazine and reading Wayne's editorials, which of course are biased. It's not like there is much information about him or his magazines in the newspaper.

Below is the latest index of L.O.S.A and you can download the
complete L.O.S.A from the following places...

WWW:

http://www.hth.com/losa.htm

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially
Guy Gustavson's story (see #001) about how he saved his beloved cat
Kesha gave me the inspiration to start writing L.O.S.A. I hope Kesha
still is alive and having a great life. Now 3 years later there are
130+ applications described and I hope you will enjoy reading all
(or parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

<snip>

Hello--
A few years ago, I wrote an article for "73" magazine in which I described a breadboarding method using hot-melt adhesive and 1/4-inch pads of thin, single-or double-sided copperclad PC laminate.

Use a paper punch to create the pads, place a sliver of hot-melt glue on a suitable substrate, place one or more component leads on the pad, and tin the copper side of a pad. The hot-melt glue bonds the pad to the substrate, and the epoxy fiberglass insulates the connection if you're using a conductive substrate (such as more copperclad).

I have used this technique to build circuits on everything from business cards to window glass. The method works remarkably well, considering the variations in glue properties-- amber "high strength" varieties work the best.

If anyone is interested in more details, I'll supply 'em.

The various kinds of Bergquist insulating pads listed in catalogs here
are all rated at several kV. There is no sign of pads rated as low as
150V.

The silicone/fibreglass type has the lowest ratings, at 3.5kV and
0.4degC/W, but others are Kapton-based and have thermal resistances of
0.2 or 0.3 degC/W.

They are all inteded for 'dry' mounting without grease, because they are
soft enough to take up the surface irregularities that grease would
fill.

73 still exists - we advertise in every issue, have been for 20 years or so. Unfortunately 73's size has fell prey to the lack of building interest in the Ham community. It used to be one of the better "neat lil construction" magazines, not on a par with "Ham Radio" magazine, but still full of fun little projects. I've seen the slow fall off in the technical expertise and 'lust' for building by hams over the years - my gosh, hitting a hundred hamfests or so a year sure has displayed that to me!

Wayne's constant prodding to the readership for more articles and experimentation seems to have fallen on either deaf ears or folks too enamored with the internet, so the magazine has withered. As much as the folks on this NG may disagree, hams have simply stopped being the ferverent pool of builders and tinkerers that they once were - and that's too bad because I *really* miss "Ham Radio" magazine and those big-as-a-phone-book 73 magazines. Look at QST, geez...build a 12 volt power supply articles?? Sure QEX is there with some great articles but hardly anyone reads it! I advertised there for about a year because I believed in supporting a magazine like that, but lost my shirt on every ad.

Sorry to carry on like this, but I think what we're seeing is the result of the relentless march of technology making building lil analog projects harder and harder (and to solder too!) There sure is lots of neat stuff to build now, but it involves high end software, little tiny chips and some pretty sophisticated test/computer equipment and skills.

I sure miss the days of recrystalling and retuning a Motorola T43 cab radio to put it on two meters!

I'm sure I opened a real can of worms here - but isn't that the object of a NG? And we've some pretty great minds here that chew the rag over the keyboard!

73, John

P.S. Mike Black's analysis/history seems like my recollection too.

Really boring people are actually quite rare. You should maybe take a Dale Carengie course to find out how to talk to people so they don't appear boring to you.

>And thanks to Ian, too, for his cleverly simple method of testing for
>loss using a microwave oven!

Hey, it's not my idea - it's almost a "standard" test method for amateur use.

If you hadn't heard of it before, please note that it's important to put a half-glass of water in the oven too, to provide a load for the magnetron.

It's also important to use a rotating turntable or antenna to make sure that the test sample doesn't stay in a location of very high or low field strength. Also, try to locate the sample at about mid-height in the oven - I usually use an upside-down glass as a stand.

This is obviously a crude test, and it relies on the generalization that the RF losses of most materials increase pretty uniformly with frequency. If a material hasn't become warm in the microwave oven, by the time the water has boiled, then it's likely to be low-loss at all lower frequencies too.

(As far as I know, this generalization applies to any material that you'd reasonably consider using as an RF insulator... does anyone know of any exceptions?)

But after having done all that, it's still possible to find circumstances where even good dielectrics will overheat and burn up: examples include loading coils, antenna tuners and the output circuits of RF power amplifiers. The difference between success and failure is often in the detail of the electrical and mechanical design, more than in the simple choice of dielectric.

great source of info is the following.

http://mot-sps.com/sps/General/chips-nav.html

another one is www.e-sonic.com go to the on line catalog, enter the
device
number, and you will get back all the info, plus the price.

Regards
Reed

Most heat sink compounds do not do well over about 120 deg Cels.
They are all about the same. They must meet required standards.

Your proper answer is to use a proper socket with cooling for hot
running lamps. The compound may end up seperating and making a mess.
It also may solidify under the heat thus locking your bulb into the
socket thus causing other problems...

I've searched the net and cant seem to find a grid protection circuit i can incorprate in the Dentron 2000L. It doesnt have a meter not really interested in that as much as some thing that will shut it down if excess drive or grid gets to high.
Thank you to everyone that has helped so far on this project have the tank circuit in and it looks good. also thank you Mr. Smith for the paper work you sent me.

The silicon rubber pads (silipads) are used along as compared to mica with thermal conductive grease (messy!)

The yellow pads are a Kapton derivative. They support much higher temperatures and somewhat higer voltages than the silipads. They don't burn.

I don't know what the clear pads are.

There's more data at www.thermalloy.com (heatsink and insulator manufacturer)

A couple of months ago, my car was broken into, and the touch tone mike was taken. Now I'm looking to hack another mike to replace it. The Alinco EMS-45 has all the buttons my old mike had, and I like the feel.

I'd like to know a few things about what's inside. At the top of the list: Do DTMF tones get generated in the mike and output on the TX audio line?

Everything else is 'hackable'.

Thanks for your help.

Hello Folks:

Would appreciate your advice on how to determine the impedance of various audio transformers that I have in my collection of junk.....er, I meant to say treasures.

I have to interface some newer, low impedance microphones to my older radios which require a high impedance mike. My collection of junk...sri, ...treasures...includes a selection of small audio transformers which may be perfect for the job, but are not marked in any way, and I can't tell what the heck they are.

All the best, and thanks for the help.

Message-ID: <01be26cb$29429ac0$672a0ccf@hannahbl>
Source record: 75865

Hello! I am trying to build a battery charger for a NiCad battery pack for the HTX-202. The project is in the 1995 ARRL Handbook, page 11.31-32. I am new to building and projects and was hoping someone could help answer one or more of the following questions. Please forgive me if they're basic- I'm trying to learn by doing.

1.The project calls for a Maxim MAX713CP single chip battery charger, which I have. Do schematics in generaly show pins in order of easiest depiction, or in the actual order the pins are on the chip? For instance, I assume the pins on the chip are, counter-clockwise from the lower right corner where the pin#1 marker is, 1 2 3 4 5 6 7 8 9 10 etc., but in the book they are shown as 11 12 6 10 9 4 3 8 7 16 5 15 2 1 14 13. I don't want to connect the pins incorrectly!

2. The project calls for a MJS2955 PNP power transistor but says this could be replaced with a smaller device (one rated for less power). This transistor was formerly carried by Radio Shack (276-2034) but isn't anymore. I have not been able to locate one by the same number from other suppliers such as Mouser and have no idea how transistors are marked or how to tell what transistors may be equivalent or of a lower power rating. Does anyone know of a suitable replacement or of where I can get an MJS2955?

3. My battery pack I will be charging is listed at 600mA. The DC wall cube power supply I have is at 500mA. Does this matter? Will the battery charge slower?

Any replies and help would be GREATLY appreciated! Thanks very much.

Chris,

I'm not sure, but I seem to remember plans for an amp in the 88 or 92
ARRL hand book that incorporated a grid protection circuit. You could
probably adapt it fairly easily. Not sure if it was an 8877 amp, but
grid current is grid current!

Good luck.

Source record: 75869

About Beryllium Oxide from a Material Safety Data Sheet I found online:

CHRONIC (long-term health effects): Inhaling dust or fumes containing beryllium may cause serious, chronic lung disease called Chronic Beryllium Disease (CBD) in some individuals. Over time lung disease can be fatal. Symptoms may include cough, chest pain, shortness of breath, weight loss, weakness, and fatigue. Long-term effects may include loss of lung function, fibrosis, or subsequent secondary effects on the heart with eventual permanent impairment. Chronic beryllium disease is a hypersensitivity or allergic condition in which the tissues of the lungs become inflamed with a cellular nodular reaction. This inflammation, sometimes with accompanying fibrosis, may restrict the exchange of oxygen between the lungs and the bloodstream. This allergic response to beryllium is limited to susceptible persons. Medical science suggests this susceptibility is related to genetic factors. Exposure to airborne beryllium does not cause a chronic reaction in most people.

CARCINOGENIC REFERENCES: The question of whether occupational exposure to beryllium materials cause human cancer has been examined extensively for over 30 years without producing any study which clearly demonstrates an association after taking into account effects of smoking and other work place carcinogen exposures. However, based on the few existing epidemiological studies and animal experimentation, the International Agency for Research on Cancer and the National Toxicology Program lists beryllium as a carcinogen.

MEDICAL CONDITIONS AGGRAVATED BY EXPOSURE: Persons with impaired pulmonary function, airway diseases, or conditions such as asthma, emphysema, chronic bronchitis, etc. may incur further impairment if dust or fume are inhaled. If prior damage or disease to the neurologic (nervous), circulatory, hematologic (blood), or urinary (kidney) systems has occurred, proper screening or examinations should be conducted on individuals who may be exposed to further risk where handling and use of this material may cause exposure.

So be careful....
73,
Dan

5691. AC hum filter. Didn't work.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-13 00:00:00 UTC
From: Sailor Man <derstine@fast.net>
Message-ID: <751khhbge1@news1.fast.net>
Source record: 75871

I need some help. A friend of mine put his dual band 2m/440 radio in his car. It transmits the alternator whine. You can tell when he is slowing down or starting off from a stop. No problem I thought. When I had my radio in my Peterbuilt truck I had the same trouble. I bought one of those filter from Radio shack installed it and it took car of the whine. Before I installed it I took it apart to see what I paid $15.00 dollar or so for, it was a few years back maybe it wasn't that much. If I remember correctly it was a coil (choke) in line with the hot line. At the end of the coil was an electrolytic capacitor with the positive connected to the hot wire coming out of the coil and the neg.. was connected to a ground. I thought I could of built that. Guess what I tried and it didn't work. I was all set to get my friends accolades and the darn thing didn't work. Now I need some input from the experts. Here what I built. Starting from the fuse block towards the radio. First was a fuse block then I wound a coil. Wanting to make sure it could handle enough current I looked around and found a old stereo cross over circuit. I used some of the wire from one of the coil in the cross over, it seemed heavy enough. Just a tad under 1/16 inch. I wound about 30 turns around a 3/8 inch wooden dowl. Then at the opposite end of the coil from the fuse block I soldered the positive side of an 1000uf 16 volt electrolytic capacitor. The negative side was soldered to a wire to be hooked up to ground. Back to the positive side of the capacitor I also soldered a wire to be hooked up to the above mentioned radio.
IT DIDN'T REDUCE THE AC WHINE A BIT!!!!!!!!!!!!! Guess I should be happy it didn't go up in smoke either. Looking for all suggestions, be gentle please :)

It sounds like your choke is the weak spot. You probably need more
turns than that, and you want to wind it around something magnetically
permeable (i.e., not wood. :-) An iron core, for example, will raise
the inductance of your choke substantially, for a given number of turns.

Using heavy wire for the choke and a good-sized capacitor at the output
is the right strategy, but a good iron core is also important. You may
be able to find ready-made chokes at Radio Shack without having to buy
the entire filter (which, as you correctly point out, can be built for a
lot less money.)

Also, please turn off HTML posting. It is harder to read (to say the
least) and it isn't compatible with the broadest possible range of
browsers.

Probably not, I'd expect an AM antenna ferrite core to saturate under
the current drain a transceiver would draw. But even so, it would
probably be better than the dowel.

> Also would it hurt to
> doulble layer the wire?

Not at all, and the wire doesn't have to be wound neatly at all for that
matter.

5697. Looking for power supply projects

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-13 00:00:00 UTC
From: "Kevin S. Beebe" <kbeebe@divide.net>
Message-ID: <751ptt$se5$1@news1.rmi.net>
Source record: 75877

Hi all,

I'm looking to build a switching power supply rated at 13.8V at 30-40A. The only project plans I can find are in the 1999 ARRL handbook which requires winding my own transformers. Yikes. I've tried that in the past and found that my own homebrew transformers do not pass the "Smoke Test". I have been largely unsuccessful in finding the other parts listed in the ARRL handbook as well (except for the ones with a specific Digi-Key Part #).

Anyone know of project plans for a 13.8V, 30-40A switching power supply that:

1) Consists entirely of parts that are readily available to the general public.
2) Have a complete list of part #'s and their source
3) Do NOT require winding my own transformers
4) Have been proven in actual use
5) Work well with Ham equiptment

Any help would be greatly appreciated.

Kevin

There are also a number of stations used for marine and aeronautical navigation operating below 500 KHz. Most are components of instrument landing ground systems and some are used to broadcast current weather information. They are located all over the country and the world for that matter.

HERE YOU GO!JUDGE FOR YOUR SELVES!

You have NO class MK!! You admit you accepted the offer! I asked for some
basic information that you did not already provide!

Kinda picky for such a lowball offer!
Realistic US lifetime
Sylvania
GE
RCA
in original boxes.
Buy 'em all or don't bother me again-GOT THAT!

Now all we need is a method for home polymerization of paraffin, so we
can make our own plastic cases and save 2/3 the cost of our projects. :-)

It's a quite simple device, but I have seen it used as RTTY AFSK
generator, LF/audio mixer, morse detector etc. It is not particularly
difficult to operate the VCO on 1kHz

Early VHF/UHF power transistors and valves seem to have the pink
coloured beryllium/ceramic, also the very popular Ex-German UHF power
triode GI7B and similar has the pink coloured ceramic

I would keep away from it, perhaps a life is not so much worth in
Russia?

Hi! I do have the tubes listed below for sale:

2x 4-400A(pull from working equip.) $40.00 each
1x 280(used) $25.00
2x 232(used,tested) $8.00 each
1x 33(pull) $3.00
1x UX-112(used) $20.00
1x UX226(used) $20.00
2x UX171A(used) $20.00 each
3x 8791(pull,tested) $100.00 each (datas available)
2x 6550(few hours used,tested,1ST & 1GT) $50.00/pair
2x 5881 N.I.B. $40.00/pair
2x 5881(used few hours only,tested) $25.00/pair
1x 2050A(new,Phillips,usa) $10.00
2x 2050A(pull,tested) $5.00/each
2x 8417 N.I.B $50.00/pair
1x 931A N.I.B RCA $20.00
3x 7360 N.I.B. GE usa $30.00 each
3x 6267 N.I.B GE $18.00 each
2x 6267(used,tested) $8.00 each
1x KT66 GEC n.i.b. $70.00
1x 272A Western Elect. NEW $60.00
6x 6JR6(used,tested,Syl) $10.00 each
2x 7C5 NIB $5.00 each
2x 6KG6(used,tested) $15.00/pair

All pulled tubes are from working equipment,unless mentionned
as new(NIB),if you are interested in some of them,
please email me for more informations.Amounts in U.S. funds.

Hey folks,

I have started a website and ISP strictly for ham operators. The idea is to get hams to help keep up a website with information updated weekly and monthly. I would like to have all the cool stuff you find on the net in one website. News, mailing lists, callsign database, if its cool I want to put it on there.

I could use someone to help keep up all different parts of the hamsnet site. Is there anyone interested in keeping up a section of the site for equipment swapping and sales of used equipment?
reply to: kc5gjn@hamsnet.net

I am also offering free e-mail addresses and web services for all ham operators.

Please go check out the site and get your free e-mail account
http://www.hamsnet.net

Thanks for your help

I wouldn't be so quick to make that association. Pink was also a
favourite colour of RCA, and sometimes the same tubes are available in
both colours.

Rick
I tried the circuit also using a bridge with varistors and also the forward bised silican diode - also didnt have much joy. I intend to stabilize the oscillator using a scheme described in Elektor a few months ago. Essentially a microcontroller is used to count the VFO signal and drive a display. It also generates a DC correction voltage from a PWM output and integrator to correct any drift. I thought this was aneat circuit which is essentioally a digital PLL I presume. Assuming the oscillator doesnt drift more than 10 Khz or so it should be OK. I was going to run the oscillator at up to 11 MHz with a swing of about 200 Khz.

Richard

but the packages for RCA 8122 valves and other contains a warning that
the ceramic must not be broken - it contains beryllium oxide.....,
a defective 8122 valve must not just be thrown in the rubbish bin.
Perhaps a reason to stick to the QBL5/3500 glass valves - at least for
2m

Cross-posted to: sci.electronics.repair,rec.radio.amateur.homebrew,rec.radio.amateur.misc,sci.optics

I want to use use some heat sink compound in a optical application to try to cool a very hot bulb. I plan to apply the compound around (and in contact with) the bulb base. I will be very careful to not insulate any electrical connections with the stuff.

I remember that 10-12 years ago there was an issue with some of these compounds separating and some of the oils running and making a mess of the circuit. Obviously, in my application I can't have any separating or contamination at all. I'd hate to try to clean up this optical device if this were to happen.

What are your experiences with these compounds? Recommendations? Things to avoid?

Sorry about my modified return address, but I hate getting spam.

Thanks,
Dave

Except that the big M had definitely quit making it in 1990 and probably
several years before that. National also made it (LM1310) and they
have/(had?) sheets for a lot of older parts in the obselete section of
their web site.

Just about everybody and their mother made it under one number or another:
Exar, National, RCA, Sprague (ULN3810), TI (SN76115), so just about any
early 1980s linear book might have it.

> be appreciated...

It's illegal, but any hybrid phone patch device for ham radio could
be fitted to the audio out/mic/PTT lines of a base CB and then connected
to a phone. Make your call to the base, and then make the phone call.
You will need somebody at the base end to set up the call.

Now, if you want _autopatch_ capabilities, the issue is more complicated,
but basically the same. Any amateur radio autopatch can be fitted to
your base station, and as long as you can access the base from your mobile,
you can make an autopatch call. You will need a touchtone generator
on the mobile to signal to the autopatch...Radio Shack used to sell these.
And of course, it's as illegal as an assisted phone patch.

Why not get your Technician amateur radio license? That way you can legally
use your local amateur repeater autopatch, with a lot fewer technical issues
and a lot better area coverage.

Dear reader,

For a ham project I need a divider that can be easily switched
between 100 and 96. Input frequency is 100 MHz. What IC I can use
best?

Source record: 75813

Joe,

Yes, 73 is still published.

I have an address for US hams to subscribe at some very good rates. Contact Bob Munhall at bcmag1@ixpres.com for the latest subscription prices. In his April 1998 list of magazines (approx 700 or so), he listed 73 for $9.50 per year. Also, CQ for $9.90 per year and CQ-VHF for $9.89 per year. He had an offer of $7.75 per year for each of these magazines to members of radio clubs.

I've converted all of my subscriptions to Bob's service over the last 10 years. When you see the price list, you can understand what the real prices for magazines really are and how Publisher's Clearing House can afford to place all of the ads on TV and load up your mail box with chances to win a million dollars.

73, Harry, W3IIT

No, I have no monitary involvement in this interprize. I luckily ran into a similiar note as this one in a local radio club newsletter.

Never tried using this in thick applications, after all, the stuff was
designed to work in very thin coatings. It might start to act as an insulator
beyond a point, and a goog air flow may be better.

That's right. Most people use way too much thermal compound. The best thermal compound is several orders of magnitude less thermally conductive than metal. It's also several orders of magnitude better than air. So the objective is to replace air, not metal, with thermal compound. The ideal amount is just enough to fill the tiny air gaps (from surface roughness), but not enough to separate the areas of metal that actually make metal-to-metal contact.

My laptop has one serial port. I need *two* serial ports, for data comms use.

Can anyone point me to a suitable hardware/software combo (homebrew design or COTS) that will let me implement this cheaply under DOS and/or Windows 95?

Because of existing applications software, it is important that the two serial ports can be addressed as COM1 and COM2. High speed is not essential -- 4800 fixed on each port is OK, and no control lines (RTS etc) are required, just TD/RD/ground.

Source record: 75818

Don,

Many years ago, I designed a frequency synthesizer operating in the VHF range (up to about 130 MHz). It used a couple of variacaps and torroid in the VCO circuit.

Initially, it made a great frequency modulated synthesizer. You could shout at it and watch the frequency shift on a spectrum analyzer. (We could also demodulate it and listen to the audio since it was the LO for a BPSK demod).

Then we decided to put a glob of RTV on the coil holding it's physical position with respect to the pc board and that pretty much halted the microphonics that were caused by very small changes in the toroid position with respect to ground.

Good point. The typical output circuit for a solid-state final is just a low-pass filter, and if the 80m waveform is not symmetrical, there will be a strong component at the fundamental. As with many other frequency-doubling schemes, the XOR gate requires a filter to remove the fundamental component.

The desired frequency coverage in the original posting was only about 3 per cent of center frequency. It doesn't seem that the final efficiency would be affected significantly by that amount of asymmetry in the drive signal. Some finals may even prefer somewhat narrower pulses rather than a perfect square wave. However, I have to confess that I haven't used an XOR gate for this purpose, but have thought that it might be interesting to try. Theoretically it ought to work.

==========
Transformers for microphones don't have to handle power , hence they
can be small in size , the smaller the better, where possible they
should be completely screened.
With mike on winding 1 and output on winding 2 : ratio (n1)^2 /
(n2)^2 = imp. mike / output impedence

Ratio n1/n2 can be determined with say 0.1 V-AC (50-60Hz) across
winding 1 -------> measure output across
winding 2

In the valve era ,modulators required a mike with an impedence of
approx 50 KOhms
However if the mike was of the dynamic type its impedence was approx.
500 Ohms. Inside the mike's housing was then a small transformer with
a winding ratio n(mike) / n(output = sqrt 500 / sqrt 50000 = 1 / 10 .
So if mike winding is fed with 0.1 V-AC the output winding would show 1 V.

With my Ten-Tec Paragon solid trx, which requires a mike with 500-600
Ohm impedence ,I use a Yaesu microphone with a tag plate :' 50 KOhm
imp.' ,from which I removed the internal transformer.

>RX

How about using a NE602 as a true multiplier. I think you can
run the output push pull to cancel out even more "stuff".

The '3359 has lousy mixer. It's designed to be used as a 2nd IF for FM,
and needs a filter in front of it. The IF also limits with an input
of 5-10 microvolts, so anything but FM will be nasty to listen to.
The IF boosts whatever is at the input to the limit so the output
without a signal is lots of noise at the same amplitude as if there was
a carrier. They get around that by having an onboard noise squelch.
(I did a SCA decoder with it, by running the oscillator at 350-400 kHz,
ftp://ftp.eskimo.com/u/m/mzenier/sca.txt).

If you don't mind losing a few dB, a simple two diode doubler
should work well. If you use a fast logic chip, 74HC, HCT etc.
You may be able to get the anti-phase outputs, directly from the
Chip.

Thanks Ken.

Hi,

OM Will, N7THL gave me this URL -

http://www.videodancelesson.com/waynesays.html#top

which should be of interest to most.

Tell you what I was wondering - I have the complete set of QST (1915 - 1997) on CDs and was hoping that someone had done the same for the rest of the ham/technical publications. So I went looking to see if maybe Wayne Green had done it for 73 (sort of 'Magnum Opus').

It is true that project building has gone into decline but there is still a hard-core out there and I don't see it ever completely vanishing; sized-down and served by small high quality publications such as QEX maybe.

Planning an 80/40m QRP cw 1W transceiver using 3.58MHz ceramic resonnator VFO tuning 3.500-3.620kHz. what is the simplest and clean solution for frequency doubler to 40m? For 80m alone I would use a CMOS CD4001 as buffer/amplifier. MC3359 seems to be an interesting device for RX

Thank you for the information. This agrees with what I had read when previously researching the topic. (I looked into it before specifying BeO as substrate material for hybrid circuits I've designed.) Several people, however, also posted cautions about getting BeO powder into cuts, and I believe even contacting the skin, which aren't hazards I was aware of and aren't included in your source. Perhaps one of the people posting these cautions could also let us know the source of their information.

My experience of varicaps is in VFO stabilisers of the so-called 'Huff &
Puff variety. (BB405 and I think BB409). I used them 'back to back' to
allow for greater VFO voltage. You can in fact use several in series to
get the capacitance swing you want. You've got to keep the DC to them
very clean. Screened, short wiring, feedthrough C's, good decoupling,
separate stabilsed supply etc., since any pick-up on this line will
modulate the VFO. Also, don't have their capacitance swing larger than
you need. i.e. if you want 200kHz swing, make sure that you use the
maximum voltage swing you have available to get it. I found from 5 -10
volts that I got a pretty linear voltage/frequency relation.
Your stabiliser sounds interesting. A long time ago I used a counter to
input the last 8 significant bits of the VFO frequency to a BBC 'B'
computer via the user port. The software to remember these and output a
control voltage for varicap across VFO tank in order to stay at the same
frequency count was quite simple and it worked very well.
Tell me, in the Elektor circuit, do you _tune_ via the microprocessor,
or is this used just to keep the VFO at the value you have chosen by
using a separate tuning control, a pot or variable C?

Roy,

I think I was one of those people. My information was from National Beryllia, a division of General Ceramics, when I talked to them about making some beryllia windows for a microwave instrument I was building. National Beryllia is the raw material supplier for most companies making products using beryllium oxide. NGK is a Japanese ceramics company that also produces raw beryllia.

What most people do not understand is that MSDS information varies by manufacturer. Some companies downplay the safety issues and other emphasize them. It all depends on what their profit motive is, unfortunately. For beryllium oxide, most MSDS information is for the fired ceramic form which is pretty inert. This is not the case for fine beryllium oxide dust.

I just found about 100 MSDS listing for materials contain BeO. Most were by vacuum tube manufacturers or heatsink companies. These were naturally the ones least likely to include the more heinous effects of beryllium oxide, as their products were generally the fired ceramic.

The carcinogenicity of beryllium oxide is an interesting topic in itself. ACGIH (American Council of Government and Industrial Hygienists) and NIOSH (Nat. Inst. Occupational Safety & Health) and a number of other safety agencies list it as cancerous. OHSA (Occupational Health and Safety Administration) does not. The permissible exposure levels are different for each agency too. Some states have their own standards too. Having worked with chemicals and their safety for a number of years, all I can suggest is that you take the conservative route and ALWAYS handle such conflicting information by taking the lowest concentration as your standard, unless you know with certainty that the data was flawed - why, and by how much.

Just to show some random information from the MSDS information I found, here are a few quotes:

Litton Industries: "may be fatal is inhaled, swallowed, or absorbed through the skin."
Thermalloy: "no hazard associated with handling manufactured forms."
General Ceramics, National Beryllia Div.: "SKIN CONTACT: PROPERLY CLEAN ANY
CONTAMINATED CLOTHING. WASH BODY ESPECIALLY UNDER FOLDS OF SKIN AND FINGERNAILS. COVER ANY OPEN WOUNDS TO AVOID INFECTION."
NGK Metals Corp.: "BERYLLIUM OXIDE IS LISTED AS AN ANIMAL CARCINOGEN CAUSING
RESPIRATORY SYSTEM TUMORS (FP N)."
Raytheon: "ALL BeO IMPLANTED IN SKIN MUST BE REMOVED IMEDIATELY."

Unfortunately my 6 volumes of RTECS (Registry of Toxic Effects of Chemical Substances) are packed away. These list the references on which studies the various exposure levels are based.

My personal feeling is that beryllium oxide insulators are not the sort of things that hams should be using. In fact, I feel that many companies using beryllium oxide in commercial applications handle it far too frequently without the proper precautions. Fortunately boron nitride is rapidly replacing beryllia in many industrial applications.

Hi Jan-Martin,

I have very good experience with balanced transistor doublers. I use a CA3028: saturate tail transistor, balanced input with transformer and unbalanced output (connect collectors via output coil to plus). With a bandfilter at the ouput you will have at least 40dB of undesired harmonic suppression. No oscillation whatsoever and even some gain. Pout max about 10 mW. I used it to about 300 MHz with good results.

We have a variety of HF mobile antennas for sale. Some are new and some
are used, as indicated.

Hustler
BM-1 bumper mount List $22 New for $16
MO-1 "fold over" mast List $32 Used for $16
MO-1 with RSS-2, mast as above, plus stainless steel resonator
spring $26
MO-3 mast - no fold over - List $24, new $19
MO-4 short mast for RVs, tall trucks, etc. - includes new tip rods -
List $20, New for $15

RM-75 standard resonator for 75 m, List $27, used $14, new $21
RM-40 standard resonator for 40 m, List $25, used $13
RM-20 standard resonator for 20 m, List $22, used for $11
RM-15 S, High Power 15 m resonator, List $25, new $19

MM-3 "Low profile" mount, standard 3/8-24, List $ 22, New $16

DCX Monitor antenna - base station discone - New, $20

Valor "Pro Am" - similar to "Hamsticks" only most say heavier duty

PHF-40, complete whip antenna for 40 m, list $24, new for $18
PHF-15, complete whip antenna for 15 m, list $24, new for $18

See http://www/gnv.fdt.net/~kenmar for more ham items for sale.

Prices do not include shipping from Florida.

E-mail to W8EK@usa.net

Thanks.

73,

Ken, W8EK

5764. FS;Eimac UHF cavity amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-14 00:00:00 UTC
From: jimmoci@aol.com
Message-ID: <19981214093353.28451.00002174@ng36.aol.com>
Source record: 75905

For Sale
Eimac model # CV-400 cavity amp for 400-512mhz.
This amp runs an 8874 tube which is good for about 600 watts on SSB and 300 on FM @100% duty cycle. (more for amateur service) It is adjustable in 10 mhz steps from 400-512mhz. This is just an RF deck and requires a HV and Filament supply. It will also require some sort of bypass relay switching setup unless it is used in repeater service. It is in good shape and comes with a very used 8874 tube (still good though) and I am asking $300 shipped cont U.S.
Thanks,
Jim W3ATV

Hi Kevin,
Look for MFJ products, there was announced switch type PS for 40A. Cost?
Down than $200.
I dont know about RFI, ask MFJ team. I am using Samlex America switching PS
SEC1212(12A contd.) for my Standard C-5900DA w/o RFI problem, and
SEC1223(23A contd.) for IC-756, also w/o RFI from 30 kHz to 54 MHz. SEC =
exellent PS for little money!

One trick you might want to try is an exclusive-OR gate like a 74HC86. The 80m signal from the CMOS buffer is fed directly to one input, and through a small RC delay to the other input. An output pulse appears following each zero crossing of the input signal. If the input waveform is symmetrical, you can get a fairly decent square wave at the output by adjusting the RC time delay. By the way, I'd use a 74HC4001 (or an unused gate of the 74HC86) rather than a CD4001. The 74HC parts are faster and have higher drive capability. The 74HC86 can be used as either an inverting buffer (signal tied to one input; other input tied to +5) or a non-inverting buffer (other input tied to ground).

If you heat magnetic material it will eventually loose it's magnetic properties. This is called the Curie Temperature. It returns when cooled though.

I wasn't aware of temperature sensitivity of these items (at least within normal temps, wahtever that is!)

Recently I built an insulated box 2"X2"X1" for a SAW filter to operate
at 55 degrees celcius. I consulted a plastic supply house and they
recommended 1/4 inch teflon as an insulator inside my metal box. I ran
some tests of heath loss and logged them by measuring the lenght of time
and frequency that the heater was on. Then I experimented with an
insulation sheet which is designed to be used behind a fire place
(this material has replaced the asbestos sheet); it looks like mortar
it is 1/4 inch thick. I got the same results as Teflon but the price is
way down. For testing electronics modules; I use one of these peltier
effect picnik coolers; I added construction foam (R-10) 2 inches

thick all around. It is very efficient because it is highly insulated.
I use the temperature probe of a digital thermometer to log the changes.
(Household inside/outside digital one). Regards! Yvon

Wakefield (was EG&G Wakefield) has a non-silicone oil-based grease that
we've found to be significantly better to use around optics; it creeps
far less, and is easily cleaned off of optical surfaces with acetone.

Harke

Yes, I am aware of this, I was hoping that a pair of 2N3904 were
satisfactory for 80m operation...
next question is: Must the input be pure sinewave or is triangle wave
satisfactorily?

I have some experience with MC1496P and SO42P, but I would like some
different and simple idea, suppose an inductive coupled bandpassfilter
is required at the output. Also have tested 2x 1N4148 two way rectifier
as doubler from 455 to 910kHz, and 72 to 144MHz, 10dBm input and 3dBm
o/p (?) Also tested a pair of grounded emitter transistors with
push-pull input, it seems to work best for frequencies under 50MHz,
balance is more critical on VHF.

73
Jan-Martin

PS. sent some notes to Reflecties door PA0KSB for 10,7MHz notch filter
(70dB) to measure oscillator phase noise using spectrum analyzer.

Lyle

Tnx. believe I have seen it mentioned earlier, didn't think of EXOR
gate. Have good experience with standard CMOS for 80m, but understand it
is close to the frequency limit if I use 5VDD. I would like to make an
experiment using 4070, 4077 or 74HC86, it just need to give sort of
square wave out. Have to use pen and paper and dream about it to come up
with an optimum solution.
Do you have any idea about spectral purity using EXOR gates? I am most
concerned about 3.5MHz break-through when operating 40m.

Would think one should need at least a single tuned filter between the
frequency doubler and output logic gate.

I assume the 'correct' time delay to produce a perfect square wave
output is 1/4 period, so if the time delay were fixed, it would produce
a perfect (mark/space = 1) square wave at only one frequency.
Is it possible to make the delay self-adjust so that one gets a
mark/space = 1 at every frequency? I am thinking that only for
mark/space = 1 is the average output volts = 1/2 the peak (usually 5v).
So some simple circuit to detect the average output volts and adjust
the time constant of the RC delay until this is 2.5v sounds feasible.

Here is my method that works fine op to 0.2 mm.

I don't use a laser printer because the toner leaves tiny
spaces between the toner powder. This poses a problem
with photo sensetive material, it does not block UV light.
Although a friend of mine uses laser printed overhead sheets
with some success by using two sheets taped together.
This seems to overcome the problem. But my methode is more
reliable:

I use an inkjet, because the ink is soaked by the paper and
therfeore does not have any space between the dots, provided
the printing resolution is high enough (300 DPI).
If posible I print out the lay-out twice the size.
With this lay-out I visit a local offset printing company
who own a lithographic camera and ask them to copy my
design to a film. This sort of camera is capable of producing
films up to 0.5 x 1 meter and can scale my designs to any size
accurately.
Because I specifically ask them to do it in their spare time,
they charge me next to nothing (last time I donated something
for their anual personel party)

With these near perfect films, a box with two UV-TL
pipes and some photo sensitive material, the rest is easy.

Hello everybody,

i would like to build a VCO running at about 2.5GHz, to work on
the ISM band. Which parts or circuit do you recomend, books, links , etc?
And the synthetizer? I'm considering national, motorola and harris
PLL's.
Thank you for your atention

Nuno Sucena

Hi! I do have the tubes listed below for sale:

2x 4-400A(pull from working equip.) $40.00 each
1x 280(used) $25.00
2x 232(used,tested) $8.00 each
1x 33(pull) $3.00
1x UX-112(used) $20.00
1x UX226(used) $20.00
2x UX171A(used) $20.00 each
3x 8791(pull,tested) $100.00 each (datas available)
2x 6550(few hours used,tested,1ST & 1GT) $50.00/pair
2x 5881 N.I.B. $40.00/pair
2x 5881(used few hours only,tested) $25.00/pair
1x 2050A(new,Phillips,usa) $10.00
2x 2050A(pull,tested) $5.00/each
2x 8417 N.I.B $50.00/pair
1x 931A N.I.B RCA $20.00
3x 7360 N.I.B. GE usa $30.00 each
3x 6267 N.I.B GE $18.00 each
2x 6267(used,tested) $8.00 each
1x KT66 GEC n.i.b. $70.00
1x 272A Western Elect. NEW $60.00
6x 6JR6(used,tested,Syl) $10.00 each
2x 7C5 NIB $5.00 each
2x 6KG6(used,tested) $15.00/pair

All pulled tubes are from working equipment,unless mentionned
as new(NIB),if you are interested in some of them,
please email me for more informations.Amounts in U.S. funds.
Thank
S.Caron Revelstoke, B.C.

73 magazine does have an E-Mail site that was listed in 73 magazine a couple of months ago as part of one of Wayne's Ramblings, but I don't know of any 73 webpage. I guess that is too high tech for Wayne. Not enough biofeedback I guess.

I have a Life Subsription to 73 dating back to 1967. My recent 73 magazines have indicated that the subscription will expire in January 99, and I have gotten a couple of renewal requests. When I contacted the outfit that was handling 73 subscriptions they indicated that the January 99 thing was just their way of handling the Y2K problem.

Being quite healthy and a careful driver, I don't think it is me that will die in January 99. Maybe life ends on the 73 side! If 73 Magazine gets any smaller, Wayne's Ramblings will be printed on an Epson & assembled with a hand stapler and mailed on a Bioelectrifier.

Joe:

When I mention some of the projects I'm building on the local repeater, some of the responses are why?? Why waste your time building something, when you can have your gizmo already made and save yourself time?? Well, I may not be able to roll my own SSB rig - atleast not yet! But I can tell you it's the educational part that I enjoy the most. Someone mentioned in a previous post that it requires expensive software, and/or test equipment to build anything these days.

<soapbox>

I think that's alot of hogwash - people want to be able to hook up a piece of gear and have it tell you what's wrong with it. The best piece of test gear is your brain, plain and simple. More than 90% of what can be built with amateur techniques can be had with a good DMM & freq counter. Most of the rigs that I look at don't even require a scope to fix. Gee, circuit board is charred, guess I need to whip out my HP scope! By using your brain and logical troubleshooting skills, it's amazing what can be accomplished. Even rolling your own PCBs is fairly easy and not too expensive to start doing yourself. Maybe it's just being lazy?? Dunno. Possibly the problem may be simple comparison. If you compare the complexity of todays rigs with all the bells and whistles, people tend to think everything is that complex. That's definately not true! Today, just like yesterday, anyone can learn how to build their own rigs. It just takes time, patience and the willingness to learn!

Mark OM,

Well said! But still, many apparently are able to internalize this
statement at all, and remain conmvinced it is "impossible".
For what it is worth, my considered opinion is that the naysayers
basically are just not interested in building. But, rather than state
that clearly, may use an excuse instead. "Too difficult", "a waste of
time", "impossible" are among the many excuses used, rather than
simply saying "I have no interest in building or learning through
building". It's like the old excuse of "not enough time", from a
person who watches an hour or more of TV a night.

73 and enjoy!

Whats wrong with verticals? Thats what the NDBs use.

If they close them down, as I said in my previous post, you could probably get some surplus antennas, along with the transmitters.

No, they are not used for instrument landings. They are used for
navigation.

Although they are sometimes used to help you find the airport when you are
flying in instrument conditions they are not classified as ILS equipment.
This would be called a NDB approach, and
are being phased out in favor of the GPS approach.

The broadcast of weather info is secondary to their main purpose

He mentioned only going to 50C, so why the need of the ceramic material?

A metal can surrounded by a couple inches of fiberglass insulation would work. In fact some hi density plastic foam, as used in house construction (usually blue in color) would probably also work at this temperature, and is easier to work with than the fiberglass (test it first in boiling water to make sure!!). Check your local building supply store.

The heating element could be as simple as a high power wire wound resistor, and I have seen application notes for the little 3 terminal temperature sensors that could be copied directly.

Well said, sparks. The autoalarm signal and what follows will most
definitely cause the motors to run faster. It is a feeling you
never quite forget as you donn the tin cans, peak the regeneration,
and crank up the gain till it hurts.

It still is there. It is taken over for Navtex related broadcasts.
I am not sure what the final disposition of the 410-500khz range will
be, but 500-524khz (or something like that) is still scheduled for
Navtex bcsts (512/518khz?).

It would be nice to get the aero bands below that when that stuff
is phased out, although I can sense one could do rather well on
450khz with even modest antennas. It is easy to hear well over
2500nm on 500khz over land or water, with only moderate output
powers (100-500w).

> Those were the days when ship to shore communications were the perview

I doff my hat to those who have pounded that brass for a living.
You, too.... ZUT!

Most had good fists, except for occasional odd swings. And, most can
still run a mean fist. Give a listen on 8364 +-, or catch the tfc lists
a little bit higher up. The ARA Free Press still rolls by QTR 1800UTC
QRG 12826R5 Sundays. The CW is scheduled to cease on 01 Feb 99, but
it is doubtful if the world fleet will be GMDSS compliant by then.
At least 25% is still non-compliant, if the union press blurbs are
correct, as of last Sundays bcst. So, CW may hang on a little longer

in the backwaters of the world. I hope so..... Listen quick, though,
or it may slip into the crackle an' din on 600M.

Hi Dale,
I've used a fiber glass fishing rod to support inverted V
dipoles with good results out up to 400 - 500 miles. The outter ends
came almost down to ground level and acted as guys for the fishing
rod.

Good luck,

Built a 30m QRP transceiver few years ago, but signals on 30m are too weak, and one need good antenna and 100W to operate on this band.

Don't have too much of this device, but have some MC1496P and S042P,
DF9IC has shown some VHF application for S042P,
MC1496 seems improved over S042P.
>
>The '3359 has lousy mixer.
One never know before testing it. I fancied the SP-750 jr (QST nov 94), but studied the 3359 tonite, it seems it is not much of the device in use for this purpose, and 3359 is quite old.

May have to to stick to LA7MI Direct Conversion Receiver for 3,5 til 3,8 MHz, see http://www.ask.hl.no/teknisk.html it has very good sensitivity (believe he mentioned 0.1uV)

studied the SP-750 jr, and thought "what would I make different", I would at least use the same VFO for 80 and 40m, and ceramic resonnators have much larger range than xtals.

I will choose VN2408 (or VN2410) FET in PA, it is easy to drive from CMOS inverter. And it seems easies to use discrete transistor FD when output must go to a tuned circuit (2.2uH and 234pF). The problem to solve is an easy switch between 3.5 and 7MHz signal, signals must not leak to RX input.

will require the rig to cover two bands. Have some experience with 40/30/20m direct conversion receiver using subharmonic diode mixer (2x 1N4148). With available LO signal on 3.5/7MHz the nearest versions are:

1) 80/40m normal DC transceiver
2) 40/20m transceiver using subharmonic mixer

Most described QRP transceivers are made by persons who must build very simple circuits, I would add some complexity, but R2 is too current consuming for portable sun cell operation here.

Have drawn some circuit diagrams for the actual frequency doublers for discussion, one showing the oscillator and a transistor pair for FD, and the one using X-nor gate as FD, they are available as b/w gif files (4 and 7kbytes).

I'm one of the people who have promoted this, and I first heard of it from Wes Hayward, W7ZOI. An inductor wound on a powdered-iron core (at least on type 6 material) at least sometimes has a lower temperature coefficient if you heat the core in boiling water, then let it cool, after winding. Both Wes and I have verified this. I treat VFO tank inductors this way. I'm not sure of the mechanism, but believe it may have to do with relieving stresses in the winding. I've heard from others who have repeatedly cycled the cores between hot and cold, but don't really know if that makes a further improvement.

I don't know of anyone who has tried this on ferrite cores, but they're usually a poor choice for a VFO inductor since their temperature coefficient is a whole lot greater to begin with.

5805. Toroidal inductor measurements

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <36777E1B.E291C83@teleport.com>
Source record: 75770

Spurred by recent comments and questions on this newsgroup, I made some inductors last weekend and measured them. Results follow.

Toroidal Inductor Measurements

Roy Lewallen, W7EL
December, 1998

Test Equipment

Inductance: GR 1606-A impedance meter. Stray series impedance was removed by initial calibration. Stray shunt capacitance was separately measured and removed mathematically. Repeatability is within about +/- 2%. No attempt was made to establish accuracy.

Q: A home-made fixture was used. This is simply an air-variable capacitor which the inductor is connected across. Coupling into and out of the fixture with signal generator and oscilloscope is done with very small capacitors. The Q is calculated from the center frequency and 3 dB bandwidth. Use of frequency counter, built-in oscilloscope voltmeter, and switchable 3 dB pad allow repeatability of about +/- 2%. Checks against a commercial Q meter show agreement within a few percent.

All measurements were made at 10 MHz.

Experiment 1: Coatings

Several identical inductors were fabricated, then coated with various compounds. Inductance and Q were measured before and after coating. The inductors were wound on Micrometals T-50-6 cores (Carbonyl SF material, relative permeability 8.5) with 25 turns of #22 wire. This just fits on a single layer.

Ind. # Uncoated Coated Coating
L(uH) Q L(uH) Q

1 2.54 281 2.54 284 None (control)
2 2.52 286 2.54 218 Duco cement
3 2.51 267 2.52 265 Standard RTV
4 2.52 280
5 2.54 279 2.55 255 Clear hot melt glue
6 2.48 268 2.55 164 "Sealing tape"
7 2.51 283 2.51 262 Paraffin
8 2.55 262
9 2.56 281 2.59 278 GE Silicone II
10 2.50 283

11 2.51 277

Notes (by inductor number):

Unless otherwise noted, coatings covered the entire core and winding, extending more than a wire diameter beyond the outside of the wire, and the center of the core was filled.

Inductances within about 0.3 uH and Q's within less than about 5 should be considered equal.

1. Inductor Q was measured several times over several days to establish repeatability. Results were 280, 281, 283, 286, 284. (The apparent trend is interesting, but not conclusive.)
2. Devcon Duco(R) Cement, allowed to dry for 24 hours. Although a generous coating was applied, the dried coating was less than a wire diameter in thickness, and the center of the core wasn't filled.
3. Dap Dow Corning 100% Silicone Sealant, Clear, allowed to cure for 24 hours. This is standard acetic-acid (vinegar) curing RTV.
5. Stanley All Purpose GlueSticks, claimed set time 25-30 seconds. These are nearly clear, translucent white, and not tan or brown colored.
6. This was some stuff I got surplus. It's a black, sticky, rubbery compound something like Coax Seal, but may be of entirely different composition. It's in the form of a thick tape. It's soluble in naphtha (and the solution dyes everything black it gets on), but acetone doesn't touch it.
7. Household canning paraffin. (I don't know what it's called in Britain, but I'm not referring to the liquid -- kerosene to us -- you call paraffin. This is a common wax made from petroleum.)
9. GE Silicone II Household Glue & Seal, Clear. This is a non-acetic-acid curing RTV. Allowed to cure for two days. Still just a little soft even after this much curing.
11. This is the same core as #6. After the coated #6 was measured, the core was cleaned, the winding cut off, the core further cleaned, then a new winding put on.

Comments:

I had made some measurements years ago, but couldn't locate the results. I recall that standard RTV was poor (lowered Q noticeably) but that an industrial non-acetic-acid curing RTV was good. The results with standard RTV in this test were striking. Either a) the formulation of standard RTV has changed over the years, b) there are major differences among brands, or c) my memory is faulty.

I recall from my earlier tests that epoxy was quite poor, but this has to be qualified after the experience with RTV. There's a huge number of different types of epoxy, and some may be much worse than others. I might test some in the future, but didn't during this test.

I intend to test Q-dope in the future, but didn't have any on hand.

Conclusions:

Of the materials tested, both types of RTV stand out as having a negligible effect on inductor Q. Hot melt glue and paraffin have a small enough effect that they should be tolerable for many applications. Duco cement seriously degrades Q, even in a much thinner layer than the other coatings. The "sealing tape", tested out of curiosity, shows just how great a degradation can be caused by a poor coating.

None of the coatings made much of a change in apparent inductance. This implies that the reduction in Q is due primarily to dielectric loss rather than simple increase in capacitance due to the material's dielectric constant.

Note the difference in inductance and Q between inductors 6 and 11, which were wound on the same core. Apparently physical differences in the windings (perhaps such as tightness and conformance to the core, or uniformity of turn spacing) are a major contributor to differences between inductors. All the cores used in the test were ordered at the same time, so they may have come from the same batch and have relatively little variation. On the basis of just the comparison between numbers 6 and 11, it's entirely possible that most of the variation between inductors in this experiment is due to winding differences. The variation might be less if smaller wire with less stiffness is used.

Experiment 2: Turn Spacing

I believe it's well established that even a partial second layer can greatly reduce the Q of a toroidal inductor. But I had recently heard that optimum Q is achieved when the first layer isn't quite full, but rather has about a 30 degree gap in the winding, to reduce the capacitance between winding ends. To test this, I wound 23 turns of #22 wire on a T-50-6 core, and measured the Q with the turns pushed close together to make a gap (of about 30 degrees), and then spread to evenly distribute the turns completely around the core. Measured 10 MHz Q's were 272 and 284, respectively. (Inductances were 2.21 and 2.11 uH.) This one test doesn't by any means exhaust all the possibilities of core geometries, permeabilities, number of turns, and wire size, all of which may play a role. But if there's any advantage to leaving a gap, I believe it would be a small one. And in at least one case, it's slightly better not to.

Another test was run using 10 turns of the same size wire on the same core. With the turns pushed together (the winding covering less than half the core), Q was 213, L was 841 nH. With the turns spread evenly around the core, Q was 209 but the L had dropped to 505 nH. I reasoned that a more fair comparison would be with a winding of about the same inductance as the original close-spaced one. This required 15 turns when distributed around the core, and resulted in a Q of 257 and L of 924 uH. Here again, the Q is best when the turns are evenly distributed. Note that type 6 powdered iron has a very low relative

permeability (8.5), so results might be different with higher-permeability materials. However, this is the material I usually use for high-Q inductors at HF, so I'm most interested in how it's affected.

Experiment 3: "Regressive" Winding

In the past, I've found what I thought was a moderate improvement in Q by "regressively" winding an inductor. To do this, you wind half the turns in the normal manner. Then you pass the wire through the hole, but to the opposite side of the inductor (with it ending up beside the first turn), then completing the winding from the vicinity of the first turn back toward the origination of the crossover. The result is an inductor with the two leads coming from points directly opposite each other. Stray capacitance is allegedly reduced by keeping the ends of the winding apart. An inductor wound in this manner with 25 turns of #22 wire measured Q = 285, L = 2.48 uH. This Q is on the high side, and the L on the low side, of the uncoated inductors measured in Experiment 1. I didn't try comparing with a standard winding on the same core, since the same number of turns wound on the same core at different times (e.g., inductors 6 and 11 in Experiment 1) were shown to come out differently from each other. My conclusion is that any Q improvement due to "regressive" winding is slight. Another claim for "regressive" winding is that it eliminates the "single turn" effect of toroidal inductors. A normal toroid will couple into its surroundings as though it consists of a single turn the size of the core. In the "regressively" wound inductor, there are two half-turns in opposite directions, so coupling should be reduced. I haven't tested this in any way, but it may be an argument in favor of the method. The relatively long wire of the crossover turn would contribute to coupling, however.

I'll undertake more experiments and measurements as time permits. I'd love to hear from anyone who has made either supporting or contradictory quantitative measurements.

Hi,

As a radio hobbyist, I very often find myself dreaming about what would be the ideal radio receiver. Sure, ideal receiver for HF is different than ideal UHF scanner... but than again, ideal receiver could do anything :-)... I would like to know if it's only me, who occasionally forgets about what can be done with current state of technology (and my pocket, too :-) and tries to imagine an ultimate "mother of all receivers".

So what's your ultimate receiver? 10Hz - 10GHz tunning range? 100000 memory channels? 150dB dynamic range? Should ultimate receiver of distant future be controllable with spoken commands ("Find a packet radio signal around 14.098 MHz and if the call sign is XXXX, log everything for me.")? I don't care how it's done, if it's some DSP mumbo jumbo or whatever they invent in future, I leave this to designers...

OK, these ideas sound crazy, so here I offer something more realistic, though probably still not possible: a hand-held unit, with _very low_ noise figure, but no intermodulation... simply connect this receiver to whatever aerial you have, and if the signal is there (ie. above the background noise) to be able to detect it. OK, this would mean that on UHF, the noise figure would have to be 0.4dB or less. The bandwidth should be controllable in some reasonable steps, for all modes. What modes? I want all of them! All voice modes and for the digital ones, I would like to be able to connect this receiver to a computer and see what is being transmitted, or even better, the receiver could have it's own display...

So what are your ideas? Or is it just me, day-dreamer, and should I just get up and go and try to learn RF and design something myself instead of whinging about how bad today's receivers are? :-)

Waiting for responses,

Roy, While I can neither prove nor disprove your theories and experiment, I think it appropriate to hand out an accolade. What you have depicted here is truly the good old fashioned ham spirit. It reminds me of the hours that I used to spend on 80mx discussing those new fangled FET things. I have printed off your findings, and filed them along with the rest of my reference material. A fine, fine job Roy. Well Done!! 73 de Glenn Inman, VE6INM

5809. mag-mount 2M antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: "Ralph J. Gable" <rgable@mts.net>
Message-ID: <3677B920.3490@mts.net>
Source record: 75774

I need a mag-mount 2M antenna. Being on a VERY limited budget I have decided to try to convert an old CB mag-mount antenna into a mag-mount 2M antenna rather than pay the $150 for a commercially made one. Antennas have never been my forte', so I am asking for some help here. How to I design the base loading for a mag-mount antenna? Any info that you can give me is appreciated.

Oh yes, I DO have toroidal cores and the stuff to wind coils with.

The other option is if there is someone with a used mag-mount antenna that they are willing to part with at a price I can afford.

Ralph,

If you cut the whip length down to 19" you won't need ANY kind of matching network, just hook the coax to the whip. It ain't elegant, but it works fine. Coax should be RG58.

5811. Toroid Coatings

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: owens@ale.atd.ucar.edu
Message-ID: <758j33$6b0$1@ncar.ucar.edu>
Source record: 75776

One coating I have experimented with is common marine spar
varnish. It does not dry to a hard finish, but remains somewhat soft
so that it doesn't break, or flake off like Q-dope does.

I did a comparison test a few years ago on a high-Q toroid
at 10MHz. The measured unloaded Q of a freshly wound coil was 350. After
coating by dipping the whole thing in spar varnish (and allowing it to
dry thoroughly) there was no detectable difference in the measured Q. I
used an old Boonton 160 Q-meter for the tests.

You just hit on one of my pet peeves.

Just because you put a 450 MHz pentium with 10 Gb hardrive in a box does not make it a good receiver!!

I would start out by making something that has top-notch RF specs. Perhaps something like:
(this is for an HF receiver 1 MHz to 30 MHz)

3rd order IM intercept +20 dBm
120 dB dynamic range
75 MHz first IF
'analog' oscillators in the front end (by this I mean no DDS. PLLs are ok if they are low noise)
Weaver style IF stages (thats the old phasing method of SSB)
Weaver style demodulation

Leave the DSP for the audio processing, if at all. Remember the human brain is the most sophisticated DSP ever devised!!!

If you want more info on good receiver design, consult the books written by Ulrich Rohde, of the Rohde & Schwarze Co. He is one of the top HF receiver designers in the world and, besides his books, had a series of articles in Ham Radio Magazine back in the '80s.

And wouldn't it be cool to have an S-meter that actually had 6 dB S-units? (Actually, most hams wouldn't like such a "dead" meter. And I'd prefer accurate calibration in dB, or better yet dBuV or dBm anyway.)

"MickeyM" <mmerm@sgi.net> wrote:
> I just purchased the Ten-Tec 6meter transceiver kit. Is there any legal way
> to modify its power output above the 5watts without an external amp?

There's no legal restriction on what an individual amateur can do
to a radio. Ten-Tec has elected to not make an internal 6m amplifier
kit available based on the type-acceptance requirements for external
amplifiers below 144MHz; apparently they believe, for whatever reason,
that selling a kit intended for installation inside a transceiver would
require type-acceptance. As far as I can tell, they're being overly
conservative, but it is possible that they have a very good reason that
isn't obvious. An amateur may build or modify an amplifier for operation
below 144MHz no more often than once a calendar year.

All of that aside, amateurs are free to build and modify equipment, with
only the above-mentioned restriction on external PAs below 144MHz. There
is *no* restriction on building entire radios, or modifying radios for
increased power output.

I have not inspected the Ten-Tec 6m radio to see if it could be fitted
with the 30W PA module for the Ten-Tec 2m radio. Given that both chassis
look identical, it may be possible to modify the 2m amplifier kit
and install it in the 6m radio, if the mechanical dimensions are the
same. If you attempt to do this, note that you may need to re-design
the 2m PA to insure correct operation and adequate spectral purity.

If there's anyone out there with the manuals for the Ten-Tec 6m and 2m
radios, I'd be delighted to have a look and see if this practical.

Bill,

My WM-1 manual states - "The WM1 needs +9 to +18 VDC at approximately 15ma." Some of them have center connector + but most are -.... you need to check before plugging in a supply.

Commercially made 5/8 wave mag mount antennas for two meters can be purchased for much less than 150 bucks. For example, TechAmerica has one on page 637 of their catalog for $29.95. Quarter-wave mag mount antennas can be found for considerably less than that.

Hi Roy!
Really great posting! Thanks for the very useful info. It comes at an opportune time, too, for I have just cleaned out some hydroscopic material Kenwood unwisely used for potting a VCO in the TS440. I was thinking of using beeswax as a replacement. Do you have any data on it? These results ought to be published in a journal.
Thanks again.

5820. FSK and PLL frequency synthesizer

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: Artur Leung <aleung@ittc.ukans.edu>
Message-ID: <367813F0.CB25D357@ittc.ukans.edu>
Source record: 75785
Cross-posted to: sci.electronics.design,sci.electronics.misc,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hi,
I have an idea about designing a FSK TX with a PLL
frequency synthesizer like the Motorola MC145170 or National LMX2316
with serial interface for programming purpose. The data rate is
relatively slow, 1200bps. My question is, is it possible for me to
re-program the R or N counter (with a fast-enough MCU) in the PLL chip
for every bit to do FSK modulation? What is the effect on the output
signal when I program the PLL chip in the middle of operation? How
feasible is this approach?

Source record: 75786
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave,rec.radio.scanner

Hi Runner,

OK I will bite:

My receiver priorities:
1) Matches my kind of operating (real-time HF CW and FSK ragchewing)
2) Cost-effective. Less than $50.
3) General coverage. Freq stability similar to crystal osc.
4) 12 dB NF, can hear < 1uV without preamp, 100+ dB dynamic range.
5) Easily repairable if required

Things that are essentially of no importance at all:
1) Type of devices used (solid state, hollow state, new, old, used)
2) Physical size and weight
3) High knob and display count (KISS)
4) "Bell and whistle" count (no use for memories, scanning, ad nauseum)
5) Physical appearance. (Performance is what matters)
6) "Warranties", "Guarantees", "resale value", "after-sales support", brand name, etc etc.

So, almost two years ago I built a receiver based on the above criterion, to suit myself. It is a direct conversion phasing receiver, similar to the popular "R2" design in Jan '93 QST. I use an Analog Devices AD9850 DDS chip as the local oscillator (LO), providing coverage from DC to 30 MHz or so. Purchased parts cost was somewhere around $35, with many components coming from the junkbox and a few from DigiKey and Mouser mail order houses. The receiver basically meets all of the above requirements and in addition provides about 50 dB of opposite sideband suppression (cannot hear the other side of zero beat on an S9+ signal) in the selected ham bands as well as excellent sounding audio. I enjoy using it mostly on 40 and 20 meters CW and FSK, along with a companion CW/FSK homebrew 40-watt transmitter. I have an instant-on pair of 3-500Z's AB1 G-G amplifier which the little 40W exciter drives to 400W out, if required. The entire RCVR or XMTR fits in the palm of my hand, so it ended up much smaller than necessary. After using it for the past year or so, it seems to meet my need for my Dream Receiver quite well.
The basic "R2" design has been duplicated by many hundreds, perhaps thousands, of op's and does not represent an exotic or conceptually new design at all. Phasing receivers have been with us for several decades now. But today it is so much simpler and inexpensive to build these kinds of designs than it was many years ago. I have been hamming for 43 years, and I believe we are living now in a Golden Age for ham radio

homebrewing, and many are taking advantage of it. Homebrewing ham gear
has never been easier or cheaper than it is today, in my view.

73,
Don, W6JL

5822. Re: Feasibility of Internet Amateur Radio Servers - A Discussion

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: John Mock <kd6pag@qsl-nojunk.net>
Message-ID: <87g1afbykt.fsf@mongrel.kd6pag.ampr.org>
Source record: 75787
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

The fact that people may not use the terminology doesn't imply that people don't want the results. People who have used packet radio for long periods of time like me for example don't think that 1200 baud even with rf forwarding is such a big deal. Better than nothing, but it is slow, and it is not always reliable either. You know it, and I note that you don't get

Ain't that the truth. I had a node walker running about 6 months after getting my license (homebrew AX25 driver w/ kit packet modem), the routing metrics aren't great. Certain paths are only intermittently reliable (and often a function of what repeaters share the radio site and the behavior of the users thereof). I basically had to do the equivalent of IP source routing to get from the S.F. Bay Area up into central Oregon, and that was strictly on a good day. This was semi-automated, so i did try it on Field Day one year (there is/was a special provision permitting digipeating and node use for packet on Field Day). I could make the connections OK (even that far away), but nobody was out there to hear my CQs.

on usenet? Most of the hams posting on here have at least one TNC and one radio capable of doing packet, now why do we use the internet instead?

Because 1200 bps AFSK packet is pathetic. It runs about as fast as a Model 33 teletype and is even less reliable. (Those old-timers who have serviced those beasts will better appreciate that remark than most...) 9600 bps ain't alot better. The satellite folks have realized that, unlike the terrestrial packet people, and many of newer birds (including P3D) will be/are 38.4 Kbps. TMSAT has already demonstrated that this works (and its images are such high quality that 9.6Kbps is *much* too slow).

What we need to do is start building compable rigs:

http://www.ee.surrey.ac.uk/EE/CSER/UOSAT/amateur/38k4_receiver_paper.html

describes the off-the-shelf approach using largely off-the-shelf equipment (the key component of which is commercial). There's no reason that someone can't homebrew a compatible device for much less money. The receiver part is immediately useful (given a suitable antenna system) and so you don't have to wait for someone else to have comparable equipment to test it out (worldwide!).

38400/1200 or 38400/9600 should work fine for client/server applications (such as BBSs, nodes and many IP/TCP applications), so a 1200/38400 node could be made which complement the homebrew 38400 modem and use ordinary rigs for the transmit side (to simplify the homebrewing and so hams no

having access to suitable test equipment won't have to worry about Part 97 compliance). And operating full-duplex should significantly reduce the retry problem with AX25 (or IP/TCP at that data rate).

-- KD6PAG (Networking Old-Timer, RF newbie)

P.S. If any S.F. Bay Area folks have an interest in this kind of home-brewing, please send me e-mail!

>Artur
>12.16.98

Feasible for very low data rates and modest deviation. I seem to
remember a range of PLL synths that support swapping between two
register sets for fast response but I can not recall who from - it may
actually have been a DDS rather than a PLL.

I am not sure how much distortion you will get at 1200 but I would
have thought significant.

If you have an AC signal (no long strings of one's and zero's you can
modulate the varactor of the VCO and set the PLL loop BW very much
lower than your lowest freq component of your data. Manchester or
other encoded data formats help in this sort of application - as they
gaurantee a transition every bit.

For low data rates you can modulate the reference crystal (presumably)
oscillator by adding a shunt varactor and usually a series inductor.

Alternatively, look at a technique called two point modulation which
allows modulation down to DC.

In the past I have found that the PLL output and hence TX phase noise
is noisy during the brief programming phase - it may have been the PLL
chip I was using and is probably related to digital crosstalk. (For
lowest noise applications I isolate the PLL serial bus to the PLL when
I am not programming it to reduce this.)

Chip: The circuit for the oven controller was in HAM RADIO for FEB 1978, pages 34-37. The author was Fred Schmidt, K4VA. I really liked the simple design, but the last few ovens I've used were modified commercial surplus that really didn't need the extreme accuracy provided by the referenced circuit.
I currently have 3 (major) projects: 1. a high perf receiver for 75m ssb
2. a high perf mobile transceiver for 20-15-10m still in the design stage
3. a qrp station using the R-2 series DC phasing stuff.
Sure wish there was more homebrew receiver stuff (high OR lo perf!!! on the homebrew newsgroup. I've recently started back through the old TUBE construction articles, looking for new ideas.

Again, good luck on your project. Drop me a line if I can help.

You could reprogram it fast enough, but the problem is whether the
PLL settling time would be fast enough, not whether the code ran
fast enough.

5827. Dielectric Coatings (part of discussion on toroids)

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-16 00:00:00 UTC
From: "Barry L. Ornitz" <ornitz@dpnet.net>
Message-ID: <c6%d2.701$H06.5045@news13.ispnews.com>
Source record: 75792

I would like to thank Roy, W7EL, for an excellent post on the measurements he made on toroids with insulating coatings. In a later post, Dave, KE9ED, asked about beeswax as a coating. Finally in private email to me, Nick, KB1DEJ, asked about stearin candlewax. Perhaps I can add a little to this discussion by talking about the chemical compositions of the different materials.

I cannot address the "black sealing tape" Roy mentioned but Duco Cement's effects would be expected. Duco Cement is a mixture of cellulose nitrate and camphor in a mixed solvent consisting of acetone, butyl acetate, and isopropanol. Once the solvent evaporates, only the cellulose nitrate and camphor are left behind. This plastic solution is actually one of the earliest manmade plastics; its older name is collodion. The camphor acts as a plasticizer to soften the very brittle cellulose nitrate. Cellulose nitrate is a moderately polar compound by itself, and the camphor is quite polar. As a dielectric, this plastic would be expected to have much higher dielectric losses than nonpolar compounds. [By the way, cellulose nitrate is slightly different from nitrocellulose in that not all of the hydroxyl groups are nitrated. It still is exceptionally flammable.]

Stearin candlewax is essentially the wax produced from animal fats or tallow. It is a long chain fatty acid mixture and is rather polar. Likewise beeswax is a mixture of fatty acids and fatty acid esters. It too is rather polar. Neither are particularly good dielectrics. I would avoid them in favor of paraffin wax which is a product of petrochemical refining. Petroleum jelly is just a lower molecular weight variation of paraffin wax that is semisolid at room temperature; it too is a good dielectric.

Roy mentioned true coil dope. This used to be a cellulose ester dissolved in a solvent (all solutions of cellulose esters are called "dopes" - I do not know why). Today this is generally polystyrene is a solvent. It has one of the lowest dielectric losses of any soluble plastics. I make it by dissolving a big bag of styrofoam "peanuts" in acetone and/or toluene. [When you first mix it up, it makes a "fuzzy" mess; allow it to sit for a few weeks for the polystyrene to fully go into solution and for various pigments and filler materials to settle out.]

I have made a cement similar to Duco Cement by dissolving cellulose acetate in acetone. This is essentially the original coil dope. The cellulose acetate is slightly less polar and has slightly better dielectric properties than the nitrate. But like cellulose nitrate, it is brittle unless a plasticizer is added. Tricresyl phosphate may be used but it hurts the dielectric properties again. I have found dioctyl phthalate (DOP) to be a better plasticizer for electrical applications but it still leaves much to be desired.

As I mentioned earlier, the purpose of the plasticizer is to act as an "internal lubricant" and "solvent which does not evaporate" to keep the finished plastic flexible. Soft, stretchy vinyl is another material that relies on a plasticizer to keep it soft. Polyvinyl chloride (a poor RF dielectric) is a very brittle material; many commercial vinyl products can be as much as 30% plasticizer. DOP is commonly used with vinyl too. As vinyl ages, the plasticizer gradually oozes out leaving the surface sticky, or it evaporates. In your automobile in the summer heat, the plasticizer evaporates from the vinyl seats and dashboard and condenses on the inside of the windows leaving a sticky, messy coating that is difficult to remove (*). In the older styles of coaxial cable with vinyl jackets, the plasticizer could leach out of the jacket and be absorbed by the polyethylene insulation around the center conductor. This is the so-called "contaminating" coax. It leads to high RF losses after a few years. Newer "noncontaminating" coax uses either improved plasticizers or a foil and/or polyester film layer to prevent the plasticizer from reaching the polyethylene.

The dielectric properties of silicones and epoxies are very dependent on the actual compositions used. Since these vary greatly with the products, it is difficult to generalize. The dielectric losses are usually less with the cured materials, however. This is especially important with one-part silicones. If you apply them in too thick a layer, only the surface will cure. This is why the silicone potting compounds are generally the two-part (resin and catalyst) variety.

In commercial epoxy circuit board material, a large portion of the dielectric loss is due to the flame retardant. This is often tetrabromo-bisphenol-A (TBBA). The standard for glass-epoxy circuit boards was generated when vacuum tubes were still popular and the flame retardant was quite necessary. With the low voltage, low current circuits of today, there has been some industry interest in eliminating the flame retardant.

"moderate" power (100-500w)? why not go the full gallon? i've dx'd the ndb band for years. many foreign beacons
which i've logged were running only 25 watts. so, why higher power? no offense intended but contact can be
routinely made with under 100 watts.

keep in mind that europe and africa use this band for their broadcast band.

Does that DDS chip provide I and Q outputs, or do you have to use external
phasing networks? If so, what are you using? How about spurs? (I'm using
a crystal VXO on mine, and would like more frequency agility.)

The R2 idea is great, but it is even better with a DSP back end. Mine uses
the Analog Devices ADSP2181 EVM , and there was one recently in QST
using the Motorola EVM. This is a great improvement over the analog opamps
in the original design. You can easily implement any filter responses you want,
and you can do a data decoder as part of the demodulation too.

> (snip...)

Three parameters: dynamic range, dynamic range and dynamic range. If
you can't get signals through the receiver without chewing them up
it doesn't matter what else happens.

For design purposes I'd look at an I/Q front end, dual low-noise
IF amplifiers, and IF DSP to tie it all together. Whether the IF
is zero (i.e. Weaver) or at a higher frequency (classical IF DSP,
or doing the final frequency conversion by sub-Nyquist sampling)
would be determined by my bank balance. :-)

Actually, there is such a magic noise blanker of sorts, it's the MFJ-1026 which according to MFJ "completely eliminates power line noise, lightning crashes and interference before they get to your receiver!" I can attest to the fact that it's an excellent unit, and it doubles as a phasing unit for 2 antennas and is also a decent active antenna.

Now as for the rest of the wishlist, dang.. we can only wish, right?

Happy DX'ing

5835. Cable Problems

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-17 00:00:00 UTC
From: "William P. Osborne" <wosborne@utdallas.edu>
Message-ID: <36791EE5.7D3E471D@utdallas.edu>
Source record: 75714

I am using an 8 conductor rotor cable (2-16 and 6-18) to control a remote antenna switch. The cable seems to have gone bad in a funny way. The wires are not shorted but have a wire to wire Z of 20 to 500 ohhms. This is based upon measuring the voltage accross the relays which are not selected, the problem occurs when this value is low enough to cause 2 or more relays to close. I have tried disconnecting the second relay contorl wire at the control box and the relay is stiill closed, but I disconnect at the remote switch and the relay opens, so it is clearly the cable, but why? HOw? Anyone seen this before?

Thanks for the info...73, Bill, K5ZQ

Source record: 75716
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Archive-name: radio/personal-intro

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to Jeffrey Herman, KH6OO, (jeffreyh@hawaii.edu), or Paul Schleck, K3FU, pschleck@novia.net.

This message was last changed on 14 March, 1998.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL

bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec.radio.info-moderator@primenet.com. Inquires and other adminis-trivia should be directed to rec.radio.info-request@primenet.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups r.r.amateur.antenna, .boatanchors, .dx, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, the older tube based amateur, military, and commercial gear, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter. The .dx group is devoted to long distance amateur communications. Each of these subgroups has its own charter and FAQ; please refer to the archives to find these documents.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

The QRP-L list is devoted to building and operating gear at low-power outputs. To subscribe, send an email to listproc@lehigh.edu and only write: subscribe qrp-l Your Name.

The TopBand e-list is devoted to all areas of operation on 160m. To subscribe, send an email to majordomo@contesting.com and only write: subscribe topband and follow the instructions you'll be sent.
This site, contesting.com, also hosts a couple dozen other ham-related e-lists. Use the above address, and only write: lists to get the entire index.

The Boatanchors e-list is devoted to the older tube-based ham, military, and commercial communications gear. To subscribe, send an email to: listserv@listserv.tempe.gov and only write: subscribe boatanchors

For homebuilding transmitters and receivers using tube technology, there is the Glowbugs e-list; send an email to:
majordomo@piobaire.mines.uidaho.edu and only write:
subscribe glowbugs <your@address.here>

The VHF DX discussion list can be accessed by sending an email to: majordomo@blacksheep.org and only writing: subscribe VHF-DX-discuss.

We now have a list devoted to amateur radio history. To subscribe, send an email to: ham-radio-history-subscribe@egroups.com - leave the body of the message blank.

Qth.net hosts over 100 ham-related e-lists, including lists devoted to each state, manufacturer, mode, band - too many to state here. Send an email to majordomo@qth.net and only write: lists to get the complete index.

For one of the most complete indexes of email lists, see the excellent web site http://pw2.netcom.com/~ac6v/pageae.html

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your

article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

From: Rajendra Abhyankar <abhyankar-dr@worldnet.att.net>
Message-ID: <36792E66.28FF@worldnet.att.net>
Source record: 75720

Hi,

I live in an apartment. I have a Yeasu FT-847 which works very
well with a Barker & Willamson AP-10 (40m thru 2 m) antenna. The
antenna is 51 inch whip with a counterpoise wire. Now the problem
I face is the following:

Neighbor has "no" TVI when I am on 2M FM.

Neighbor has TVI when I am on 10m ssb (or HF bands in general).

I was wondering if I should add a one of the "low pass" filter
between my antenna or should I add a TVI (high pass) filter on
my neighbors TV ??? Or do both ?? (when operating on HF).

Would appreciate your advice.

Thanks.

Raju

Has there been any lightning in the area?

My first guess is a close strike caused an arc through insulation somewhere, creating a low-resistance carbon path. (basically the same thing that's inside a resistor!) I've seen this happen at the base of a rectifier tube, though never on a cable.

It doesn't sound possible from the way you describe the connections, but if you have a connector at either end, is it possible there's some kind of semi-conductive contamination inside the connector?

Has the cable possibly been damaged (maybe by animal bites? Or by being pulled too tightly around a turn?) somewhere? Though I'd think that kind of problem would yield a lower resistance..

5843. FS: Caddock noninductive resistors, more (long)

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-17 00:00:00 UTC
From: Brad Thompson <Brad_Thompson@pop.valley.net>
Message-ID: <3679324F.2379@pop.valley.net>
Source record: 75722

FS: Caddock resistors (and another useful wirewound resistor).

If you need more information or would like to view a ZIPped BMP
(bitmapped format) image of the two resistors (a 275kB file), please
contact me at the address shown at the end of this message and I'll
forward the file and an e-mail attachment.

73,
Brad AA1IP

****
Caddock MS281N type:

10 ohm +/- 5 per cent tolerance, 8 watt noninductive power film
resistors

Tinned axial leads (0.75 inches long) are formed for PC-board
insertion on 1.2-inch centers. These are NOS, bulk-packed parts.

Note: these measure well within tolerance at +/- 0.2 ohms typical. Full
specs are available in PDF format on Caddock's web site
(www.caddock.com)
but highlights are:

--Temperature coefficient of resistance: 50 ppm;
--Power rating: 8 watts at 25 C, derating to 4 watts at 150 C and
0 watts at 275 C;
--Noninductive design: serpentine film layout cancels magnetic field-
equivalent inductance of a straight piece of wire of the
resistor's body plus lead length.

Applications include:
--Current sampling;
--Cathode bias;
--Dummy loads for audio and RF applications.

Price: $1.50 each ($12.50 for 10 pieces); only 102 pieces available

****

FS: Rockwood wirewound resistors

1.8K +/- 10 per cent tolerance, 3 watt

Tinned axial leads (1.5 inches long) are formed for PC-board insertion
on
1.0-inch centers. Resistor body is of square construction. These are
NOS,

bulk-packed parts.

Use for general-purpose voltage division, screen current-limiting or wherever a resistor with more power-handling capability than a 2-watt carbon composition resistor is required. Definitely not in Caddock's class, but these are a basic barrel-of-nails resistors.

Price: $1.00 for 10 pieces ($8.00 for 100 pieces); several thousand pieces are available!

****

And... yet another offering of these ever-popular six-lug terminal strips, similar to Keystone's p/n 825: six isolated, tinned steel lugs mounted on a brown phenolic insulating strip, arranged in groups of three on either side of a central mounting bracket.

The lugs are spaced on 0.375-inch centers; mounting bracket has a 0.140-inch hole (use a 6-32 screw for chassis mounting).

Prices: $8.00 per 100 pieces, $15.00 per 200 pieces, $45.00 per 1,000 pieces (plus $10.00 for priority-mail shipment. (U.S. only)).

****

Postage: Add $1.50 for 10 or fewer pieces sent via first-class mail;
Or...
Add $3.75 for insured U.S. Priority mail shipment of up to 100-piece quantities of any component; inquire for postage charges for larger quantities.

I accept payment via personal or cashier's check or money order drawn in U.S. dollars and made payable to "Brad Thompson".

Overseas purchasers: let me know your location, and I'll calculate appropriate postage.

If you purchase these components and find them unsatisfactory upon your inspection, return the components (unused) for a refund within seven days.

These components are subject to prior sale and are supplied as-is, as new-old-stock (NOS) merchandise, with all responsibility for safe and successful application residing solely with the purchaser.

Is the cable buried or above ground?

Have you inspected every inch of the cable to check for damage or
deterioration?

The rotor cable that I have seen has PVC insulation, which may deteriorate
in sunlight after several years.

Are the ends of the cable sealed from weather? Perhaps some water got in
and is corroding the connections.

: between 100 and 96. Input frequency is 100 MHz. What IC I can use
: best?

The 74AC parts are spec'd to work at that sort of frequency. What I'd recommend is an initial divide-by-2, followed by a selectable divide-by-50 or divide-by-48, which could be done with the 160-series of presettable counters easily. The intial divide-by-2 gets you to a clock (50MHz; 20nS period) that allows enough setup time in all cases, I think... It probably would be marginal at best at 100MHz straight into a pair of 160-series counters. (You could also do an initial divide-by-4, then a divide-by-25 or 24, and have LOTS of setup time available for the counters.)

If this is in an application where low jitter is important, try to re-synchronize the output to your input clock (with something like a D flip-flop clocked from the 100MHz input). Around here, the AC logic has a reputation for being very low jitter and a good choice for PLL dividers.

Hi Gary,

I am using just the simple-minded analog approach, with no DSP back
end. Remember, flexibility is not one of my high wants. I'd like to
play with the DSP one of these days, but other projects, particularly
antennas, take priority right now. Once I get something going that I am
happy with, I tend to stay with it for years, HI!
The RF phase shifting to obtain the Inphase and Quadrature drive for
the balanced mixers is done on a per-band basis. On other bands, with no
RF phase shifter, you can easily use the receiver as a non-image
cancelling (both sides of zero beat audible) receiver, which actually is
still very useful I have found. I operate only two bands and two modes
(CW, and some FSK/TOR) for over 95% of my operating time, so my needs
are simple.
I have used both an LC LO and the DDS chip LO, and listening on bands
and looking for birdies, I can tell no difference whatsoever when
switching between the two, at least over the HF spectrum. I've even
listened with it using no front end preselector whatsoever (antenna
directly into the in-phase power splitter), and it works surprisingly
well. That is the extent of my 'spurious response' testing, but it
seems to meet my needs.

I have used Radio Shack mag mount for 2 meters (5/8ths) and done very well
with it. I go 80 mph on highway with no problems. Used 2.5 watt HT to hit
local repeaters and for local repeaters while traveling through New England.
Had good qso's and guidance to locations I requested on the repeaters.

Interesting, Doug. About a year ago I had to replace one of the LED's
in the controller after a strom, indicating some lighting I think. But,
the cable did not fail for sometime afterwards, however I think it did
start to fail when the ground got wet for the winter. Your theory seems
the best I have heard.

5853. R2 quadrature LO?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-17 00:00:00 UTC
From: "D. J. Wang (KE3ZB)" <ddw2@lehigh.edu>
Message-ID: <367972B3.26B9@lehigh.edu>
Source record: 75732

This is probably the best time to ask this question since so many
experts are on the R2 subject.
Has anyone tried to generate the quadrature LO for the R2 (direct
conversion receiver) from a UHF/VHF source using flip-flops like 7474?
Since the diode double balance mixer would not mind "square wave" signal
I guess it will work. Is there any problem for such design?

Thanks and 73.

DJ Wang/ KE3ZB

Are there any tries to use a soundcard to receive the signals?

I doubt if most sound cards have a high enough sample rate. To process a
38.4 kbps signal, Nyquist says you'll need at least twice that in terms of
a sample rate, e.g. about 80 kHz (with good filtering) and most sound cards
operate at the CD sample rate of 44.1 kHz. Maybe an EZKit will run that
fast, but not your typical cheap sound card.

There's a neat article in Communications Quarterly that uses the 4066
cmos quad bilateral switch for the mixer in a direct conversion
receiver. The neat thing, of course, is that it is insensitive to the
shape or power of the LO signal. The designer claims it works well to
30 MHz. The 'trick' is matching the input to the 4066. The other trick
is finding the magazine. I found it at Barnes and Noble. Don't bother
with the corner news stand, this is a $10 magazine!

You have to be careful with a lot of the power amps. Many of them are
internally matched for a given band and work poorly, if at all, outside
of the design band.

> fast enough.

Settling time is an issue, but probably not as important as the
overshoot and ringing. You'd have to carefully design the loop filter
to avoid overshoot while maintaining adequate bandwidth for the desired
data rate. Overshoot, by the way, is a fairly significant in most
of the PLL rigs I've looked at. They come bouncing onto channel,
often with a significant component +/- 30KHz away. If this was
happening on every data transition, you'd make other local amateurs
unhappy.

You probably couldn't use the typical single-loop topology that is
commonly found in VHF/UHF radios, but I haven't done the math to
get an idea of what the boundaries are.

By the way, my old Kenwood TR-2600A had a *horrific* overshoot, it
was clearly visible +/- 100KHz away.

Actually, I would want three receivers (maybe all in the same cabinet?). I
would like decent sensitivity for long wave (10kHz-520kHz) with some kind of
"magic" noise blanker that would get rid of power line noise, hash from light

dimmers and touch lamps and be quick enough to almost get rid of summer time lightning static. The medium wave/short wave (520kHz-30mHz) section should have no overload problems and be able to select a DX station right next to a local with no problem. Oh, and it should have multiple bandwidth selections, receive AM, SSB, CW, Packet etc etc and have better than .1 microvolt sensitivity. The VHF-UHF (30mHz-2100mHz) section should also have at least .1 microvolt sensitivity, receive narrow and wide FM, AM, digital modes and please, no locked out cellular or PCS bands!!! I think I could get by with about 6000 memories - all with 80 character alpha display. Also have to have decent (I mean real good) audio quality. Also have to have AM stereo for MW and stereo and RDS for FM. This radio should be able to scan 400 channels per second and have "dual band" receive so I can scan the local police and fire department while DXing the AM broadcast band. I would want it to be portable, run at least 100 hours on 4 AA batteries and most important, be in a price range that we can afford. No matter what, I'm sure the "perfect" radio will never be invented but you are right - it is sure nice to dream every now and then. 73, Rocky.

The micro counts the signal - if it has changed since the last count it
generates an error via a PWM output and integrator
I presume it is a sort of a digital PLL

Artur
The major problems you have to face are
1. Noise during the serial programming transitions .If you have a receiver
you will hear this.
This will possibly confuse your demodulator
2. Loop filter requirements should be reevaluated . A pll has many
parameters to be taken into consideration (eg. overshoot,reference
rejection etc)
All these things are to troublesome to cope and you should have a spectrum
analyzer at least to see the results

For low baud rates try modulating your reference instead its more easy and
straight forward . Just modify your loop natural frequency so it
follows the modulation

Looking for a FNB-5A or 5B penlite pack (i.e. AA size dry cells)
for the Yaesu 727 handheld (among others).

It's the penlite version of the FNB-4 series nicad pack.

I'd like to have one in hand before New Years - I's like to have it
as a backup for my nicads for the New Year's Day Rose Parade.

<snipped> better than .1 microvolt sensitivity.

You really want to have an *S9 plus* background noise all the time??
Rather defeats the idea of an ideal RX. Anything better than around
2 microvolts is over specced.

Just had an idea. Maybe you are using wet string as an aerial??

Good ideas! I would like to add a few: CTCSS and DCS capability with
tone scanning to search for unknown tones, data decoding (MDT
protocols, paging protocols, etc.), CW decoding for fast repeater ID's
(I can't copy 20wpm!), battery and signal strength meters, trunk
tracking of all known trunking systems on ANY frequencies (not just
800 MHz), ability to monitor more than one trunking group at a time,
ability to monitor both trunking systems and conventional freqs. at
the same time, and digital decoding.

Do not send email. This account has been set up to reject all email
due to the recent actions of spambutts.

This is from the FAQ page on the Svetlana web site:

>Q. Why is your ceramic pink?
>A. Svetlana ceramic power tubes are manufactured with high-purity,
>high-alumina ceramic with chromium and manganese additives. The
>combination of chromium and manganese with high alumina ceramic results
>in a true chemical bond in the metal-to-ceramic brazing process. These
>additives also give Svetlana ceramic tubes their distinctive
>appearance.

So there you have it: the pink color does NOT automatically mean
beryllia.

Because beryllia is toxic, it is is only used where there is a real need
to conduct heat from one location to another. In a transmitting tube the
aim is to keep heat from the anode *away* from the grid structure, so
beryllia ceramic is the last thing you'd want to use for the main anode
insulator.

It's much more likely that the beryllia in an 8122 is on the inside,
maybe somewhere around the heater - hence the warning that the tube
should not be broken open. The RCA (now Burle) application notes
actually recommend cleaning arc marks off the external ceramics using
abrasives or even sand-blasting!

There are no warnings about beryllia, except in the section that
specifically deals with thermal links for conduction-cooled tubes.

Thanks for the reply, your answer is a bit over my head.

I can only adjust a variable capacitor on each half of the coupling
cap. This tunes the resonator on each half.

From what I gather, set the freq source midband and peak the resonators
using the variable caps for the strongest signal in the scope.
This means that each resonator is tuned to the same frequency, correct?

thanks
Fred

Just to check my understanding here, the problem would be that if he hooks
it up to a load
that isn't 50+0j Ohms, the load will detune the filter, yes?

> It would be a whole lot easier if your generator can accomplish

(Nick also emailed these questions to me, so he got the long version
in email...but...) yes, it can change both the tuning and the loaded Q.
The latter can have significant effects on the overall filter shape.

: This is, essentially, a crude network analyzer, right?

Yes, magnitude only. And if you don't have a scope that covers the
frequency you're sweeping, you can build a simple diode detector
and use that to drive the scope. Have to be careful about having
enough signal to keep things reasonably linear, and have time
constants appropriate to your sweep rate so the detector output
really follows the filter response.

Yes, since you don't have access to the coupling, just peak each
resonator. Actually, what I'd recommend is to connect the filter as
you're going to use it. I assume it's going between an antenna and
a receiver. Then connect the generator (with low output level!!)
to an antenna a few hundred feet away. Perhaps a willing neighbor
would help you out by tuning the generator to the freqs you request?
And then check that you get a reasonably flat passband over the range
you want. Try just peaking the response at the center freq by tuning
each cap in turn, then checking toward the edges of the desired band.
If the filter attenuates too quickly toward the band edges, you can
correct that by tuning one resonator a bit higher and the other a
bit lower; but if you get two peaks with a "valley" between after
the initial tuning, you probably won't be able to change it...

By tuning "in place," then you _know_ what the actual response is.
Too much can change between idealized 50-ohm terminations and what
you really have in the installation to rely on just that way to
tune it, if you really care about the response.

5887. Power supply Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-18 00:00:00 UTC
From: Terry Anderson <tlan0@runestone.net>
Message-ID: <75egee$jl8$1@news3.mr.net>
Source record: 75670

Seasons Greetings!

Wondering if anyone has any ideas as how to build or buy a power supply for a RF amp project of mine.

Heres the Scoop, Iv'e got this idea for a all electronic rf amp that would have a 1200watt output for the hf ham bands. Got most of it figured out, it's just it needs to have a power supply.
the power supply has to have atleast 60 amp output and voltage of 44 to 55 volt. Would like to have the voltage adjustable in that range, but can't seem to find any info on an adjustable voltage regulator, chip or otherwise. Thought at on time could use a regulator circut with a zener diode,but no info on that either.
Was looking at a diagram for the Pyramid supply witch uses a 723 regulator chip to control the base on the pass transisters to regulate the output voltage.
But not sure if that would be worth the trouble.
Power supply has to run 45 to 55 Volts @ 60 amp or better.

Any one with some ideas? Your input on this thought would surely be Welcome!

Please e-mail me direct or to the newsgroup.
tlan0@runestone.net

Thanks
Terry N0XHC

Another important parameter is VSWR! Minicircuit Lab has a series of SMT attenuators. For VHF and UHF, the "LAT" series is fine. I have used them and got excellent results. When designing a switchable attenuator, a problem arises due to undesired capacitance and inductance in the switches and wiring. Building a switchable atteneuator
beyond 200 Mhz is an art if the VSWR desired is below 1.2:1. If you have access to a VSWR Bridge, the best way is to terminate your attenuator into a low VSWR termination and trim the VSWR using low values of NPO capacitors in between each switch. Regards!

perhaps it is this...
The miniR2 was described an article in the Nov. '95 issue of QST
entitled "A Small High-Performance CW Transceiver", and also in the ARRL
book "QRP Power".
Believe I have the magazine somewhere, but it seems to have vanished,
would it be possible to scan the circuit diagram and send as gif or jpg
file?

I'm trying not to waste my time in there at the moment so I'm not sure if they still carry them. Last time I went in to buy a modem there were no recognizable brand 56K ones on the shelf that didn't have those "hey so what if the box is open, the product's perfect, trust us" labels.

I tried a couple of times to bring the BeO issue to the attention of store managers but they just didn't want to listen. They have a prop 65 sign posted (sorry the rest of the world that's a California joke) so they are probably immune from lawsuits anyway.

I use the glass from Coleman gas camping lanterns with my 4-400s.
They come in two sizes, I'm not sure if the larger one will
fit over the 4-1000 or not.
They are cheap (like 1/10th the cost of what Eimac wants)
so you could get one and give it a try.
I got mine at the sporting good dept. at Wal-Mart.

5900. How do I tune my double-tuned bandpass filter?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-18 00:00:00 UTC
From: fred@internet_cafe.net
Message-ID: <aghe2.4090$_c.11902946@newsgate.direct.ca>
Source record: 75744

RE: How do I tune my double-tuned bandpass filter?

I am not a HAM but hope here someone can assist me.

I have a 30 mhz double-tuned bandpass filter and I want
to set the variable capacitor to peak the resonator for
each half of the filter.

I have a 50 ohm, 30 mhz rf generator and it has a 14 decibal pad
on the output so it will not harm the filter. I terminate the filter
in 50 ohms and then hook up my scope.

My question is what frequency do I set the signal generator on?
My filter is designed to cover 30.00 mhz to 30.5 mhz. Do I peak
each resonator seperately at the 3 dB bandwidth designs or midrange
between the bandpass (30.25 mhz)?

Please explain procedure.

many thanks
Fred Hunter (SWL)

5901. Resistors for attenuators

Something that's important up front: if you use a 50 ohm source
and a 50 ohm load to tune it up, you'll want to use it in a
system where it sees a 50 ohm source and a 50 ohm load. Usually
receivers aren't very good 50 ohm loads...and similarly, antennas
may not be good 50 ohm sources unless you use have an antenna
tuner: but how do you tune the tuner to guarantee 50 ohms unless
you have a SWR bridge? ... OK, things might not be TOO bad
if your impedances aren't too far off of 50 ohms.

The tuning method can depend on just how the thing is constructed.
Do you have a coupling adjustment as well as a tuning adjustment
for each section? If you could start at zero inter-stage coupling,
you can tune each section to the desired center frequency, then
increase the coupling until the response at the center freq
just starts to decrease; if you go a bit beyond that, you
should see a slight dip at the center freq and a peak on either
side of that.

It would be a whole lot easier if your generator can accomplish
a sweep from maybe 29MHz to 31.5MHz, and sync your scope to the
sweep, so the scope displays frequency on its x-axis. Then you
can immediately see the effects of your adjustments, and you can
go for the desired response.

(There are actually five adjustments that come immediately to mind:
coupling from input to first resonator, tuning of first resonator,
coupling from first to second resonator, tuning of second resonator,
and coupling from second resonator to load. The first and last
of these, and perhaps the middle one as well, may be "fixed" in your
design, but they affect the bandwidth and the response curve
significantly.)

: Where can I find resistors for building 50 ohm attenuators? These need
: to be precision resistors with very hard to find values. None of the
: normal distributors (Digikey, Mouser, etc) seems to carry them.

What frequency range? What power level? I seem to recall that
DigiKey has a range of 0.1% surface mount resistors now, that would
probably work very well for an attenuator up to hundreds of MHz
if constructed carefully. Rather limited power, of course. But
I doubt you need 0.1%! Certainly 1% would do fine? The usual
method to get the values you want when you can't afford to
special order exact custom values is to parallel or series values
that get you what you want.

If you're really rabid about precision attenuators, you can get
little SMT 50-ohm attenuators, the nice little matched set of
resistors for various particular attenuations, that are good to
frequencies way beyond anything I play with so I'm not sure how
many GHz they are good to...

For mid-power, I've measured some pretty darned low parasitic L
and C values for the 2-watt metal-oxide resistors, and have built
attenuators with quite acceptable (to me) performance to 450MHz.
And yes, I do have access to equipment I trust to do a good job
measuring both the components and the resulting attenuators.

That would only be true if BPS = baud. As telco modems demonstrate,
that doesn't necessarily have to be so.

I don't know how precise an attenuator you're trying to make, but I think you'll find that ordinary 5% resistors will get you within a fraction (in dB) of the attenuator setting. At high frequencies, you're likely to get more error due to stray inductance and capacitance than from a few percent variation in resistor values.

For 38.4 _kBaud_ signals you would require about 80 kHz sampling rate.

Is this 38.4 kbit/s satellite downlink signal really two level (38.4
kBaud/s) or four level (19.2 kBaud/s) or eight level (9.6 kBaud/s),
which would determine the bandwidth and sampling rate required.

Definitely, they are shown to make drawing the schematic as simple as possible.

Also, NICADs generally charge at about 10% the rated output. For example a 1 Amp-hour battery would safely be charged at about 100 mA. Faster chargers have to have overtemperature safety devices.

As Roy and Tom have pointed out, "accurate attenuation" usually means within 0.1dB, and this is quite easily achieved using standard resistor values.

Here is a set of useful attenuators that can be made from standard-value resistors. They are all pi-networks: R1 shunt to ground, R2 in series, R3 shunt to ground.

Nominal R1,R3 R2 Theory (in a 50 ohm system)
atten.
1dB 910 5.6 0.98
2dB 430 12 2.07
3dB 300 18 3.02
6dB 150 39 6.16
10dB 91* 68 10.08 * 100 paralleled with 1K
20dB 60* 240 19.9 * two 120, paralleled

For a low-power attenuator you can use small wire-ended metal film resistors, cut to 'zero' lead length (just the minimum necessary to solder to). You can easily make a switched attenuator set using small slide switches, carefully spaced to require minimum lengths of connecting leads. By switching sections in and out, you can get attenuations ranging from almost zero up to 42dB in 1dB steps. Various ARRL publications have shown how to make a box from PC board material, with screens between the sections.

For a box built that way, using 1% resistors, the attenuations of individual sections will be remarkably accurate. They will probably remain very close to the theoretical values up to at least 100MHz. Above this frequency, the inductance of the resistors and connecting leads becomes important, and the attenuation tends to rise above theoretical; but it can still be within about 0.3dB, even at 432MHz.

Obviously results will vary, individual construction methods being more important than the choice of resistors, but it certainly can be done well using readily available components.

Thank you for reading. I would like to homebrew a "duplexer" to combine the 144 and 220 MHz outputs from my mobile rig into a homebrew dual band antenna. Anyone have any good circuits for making a duplexer network? Thought I saw one a while back. My guess would be a low pass pi net for 144 coupled to a 220 hi pass pi net. Second guess would be "coupled resonator" filters for each band.

Most of the R2 and T2 papers are reprinted in the book "QRP Power" which is
sold by the ARRL. The blurb from the ARRL webpage goes:

Whether you've just been bitten by the urge to operate flea power, or you've
already discovered just how much fun it is to operate with 5 W or less, QRP
Power is just what you've been looking for. It's crammed with projects you can
build and resource information you can use. In addition to the best recent
QRP-related articles from QST, QEX and The ARRL Handbook, there's a new,
in-depth article on NN1G's popular 40-40 transceiver. 1st ed,
©1996, 208 pages, #5617--$12

You can order it from their webpage.

The article on using DSP with the the R2 appeared in the April 1998 QST, and
was titled: "A High-Performance, Single-Signal, Direct Conversion Receiver
with DSP Filtering.". The article also appears as a link on the following
webpage.

http://www.wwc.edu/~frohro/R2-DSP.html

In general, I find the R2 and matching T2 modules to be very interesting and
well suited towards experimentation by the digital experimenter. I also
recall that the SETI league has a modified version of this receiver (wider
receive filters mostly) that they are using for their work.

As frugal as I am, less than $50 borders on "cheap" rather than cost effective. Perhaps $300 - $500 might be more reasonable for all the neat features that the clever people of this newsgroup suggest for the ideal receiver.

Oh, I don't know about that. A 450 MHz Pentium II makes a fine DSP platform.
You can program a VGA card to serve as the LO (even supply quadrature with
two output channels (say red and green), the sound card works as the I/Q
input from the mixers, etc. All you need outboard is a pair of DBMs and perhaps
a preselector/attenuator. The rest is just software. :-)

>Since the diode double balance mixer would not mind "square wave" signal
>I guess it will work. Is there any problem for such design?

Yes, the problem is symmetry. The squarewave drive has to be very
symmetric or you get lots of distortion products in the mixer. This
limits you to frequencies which are exactly divisible by 2 as input
to the divider flip-flop. There is also a jitter problem with the divider
where it doesn't change state exactly at the 50/50 point every cycle
IE hysteresis. This also causes distortion.

DBMs actually prefer squarewave LO drive, but the above mentioned
symmetry problems make use of a sinewave LO the better choice.
A simple LC tank can guarantee good symmetry from a sinewave.

Settling time is an issue, but probably not as important as the overshoot and ringing. You'd have to carefully design the loop filter to avoid overshoot while maintaining adequate bandwidth for the desired data rate. Overshoot, by the way, is a fairly significant in most of the PLL rigs I've looked at. They come bouncing onto channel, often with a significant component +/- 30KHz away. ...

By the way, my old Kenwood TR-2600A had a *horrific* overshoot, it was clearly visible +/- 100KHz away.

Yep, and a good reason why one is expected to use type-accepted rigs outside of the ham bands (except during serious emergences). Or, if one uses commercial frequencies routinely, to program a few amateur channels, in addition to one's allocated channels, into one's personal commercial rig. [This applies to Part 97 users, other countries may vary.] At least, that's what to local techs i know do about that problem.

There's a homebrew diplexer described in _QST_, Oct 1991. I built one from sub-optimal parts that works fairly well at 2m vs. 70cm. Formulas are included for other bands, but i wouldn't be surprise if 144 MHz and 220 MHz are too closely spaced for that design.

-- KD6PAG

P.S. If you can't get that issue conveniently, here's at least a description of the circuit, so you can see if it's worth the trouble to track it down:

http://ftp.barc.org:8080/pub/hamradio/arrl/infoserv/techmisc/diplexer.txt

I got mine (2/3 C??) locally to rebuild a non-sighted ham's battery pack, at HdB Electronics, 2860 Spring St., Redwood City, CA 650-368-1388. Yes, they have a catalog, and i believe they do mail order. And i found their prices for such things very reasonable. Being able to match batteries in person is worth a higher price, but in my case, i paid a lower one. Power One is a matter of blocks away, so that probably helps keep their prices low.
73's and good luck,

Hi Net Folks,

I just bought a copy of the Arrl Radio Designer software, and I can't get it to run at all. It locks up my computer immediately when I try to run the program. To be more precise, it shows a full screen window, title bar, menu bar, and splash screen, shows an hour glass cursor for about five seconds, and then does nothing further. Nothing happens if you click on any of the menus. You can't switch tasks. The mouse moves, but keystrokes and clicks are not accepted by the computer. Sometimes I can get control with Ctl-Alt-Del, and sometimes I must hit the reset switch.

I tried stopping all tasks except explorer and doing the installation again. Same result.

Any help would be greatly appreciated.

Is there a mailing list or support group for ARD?

Thanks,
Bert Douglas

I was in my local Active Electronics today, and looked at the ceramic heatsink washers they sell. The ones for TO-3 and TO-5 packages were labelled beryllium oxide, but the TO-220 ones were labelled aluminum oxide. There was no visible difference between the materials.

Does aluminum oxide make a good heat conductor? I know it's a good insulator.

Believe it or not, Radio Shack sells nicads with solder tabs, including
sub-C cells if I remember correctly.

You might also check for specialty battery shops that will do the whole
job. There are several places in this city that will rebuild the pack,
welding together bulk cells, for less than just the cost of the cells
with solder tabs. (You don't need the solder-tab cells if you have
welding equipment).

Aluminum oxide has only about one tenth the heat conductivity of beryllium oxide. That's why BeO is used in spite of its toxicity.

Both are excellent insulators, having low loss even at microwave frequencies. Alumina has a higher dielectric constant, 10, as opposed to about 6 for beryllia. So for a given washer thickness, alumina will give you more capacitance to ground.

I didn't realize that anyone made alumina heat sink washers.

Its almost all been said except for paralleling (10?) VHF hi Q low cost
hyperabrupt junction to get a sensible value for HF, it wont improve the
TC but will improve cost and spectral purity when compared to high value
varicaps.
Note TC increases at low tuning voltage so you have the decision low
volts+ hi slope padded by evternal c with good TC or Hi control volts
alone.
Control voltage noise could be your greatest enemy.

Solid State Design For The Radio Amateur (ARRL) is
the home brewers bible. Ham Radio Nov. 1984 had
an excellent article, describing a 6Mtr RX front end.
The ARRL Handbook is full of good construction info.
The 1999 edition is probably in print by now, so you
should get a very good discount on the 98 edition.

Bert, you may have a video driver conflict.

Try resetting your video to Windows' standard VGA -- 640 x 480 and
test the program. If that clears the problem check the Web site of
the manufacturer of the video card for an updated driver.

You might try rebooting into the "Safe" mode of Windows. This will
default to VGA and load only the components of the operating system
necessary to let it run. You'll likely have no CD-ROM driver, network
software, or anything that is not "vanilla" Windows.

Hope this helps.

I don't think you will have much luck trying to heat sink the bulb. i am
assuming it is made of glass or quartz. Trying to cool the bulb in this
fashion would place too much stress on it and probably would develop
cracks in no time at all. I think you would be better off placing your
efforts into developing a air cooling system. Afterall look how they do
it with movie and overhead projectors.

In other words, the "aluminum oxide" heat sink insulators I saw were
probably really beryllium oxide, mislabelled by someone typing the wrong
thing into a database somewhere.

Homebrew Paradise - everything you always wanted to know about radio homebrew (and distillation)

Yep, it has been a long time time since I posted an update, mainly because I have been quite busy these days. With up to 400 visitors A DAY you can imaging the amount of E-mail I am getting! One day I will post some of it. I have had a few laughs. For example " ... and can you design, build and send me the PCB foil pattern and schematics for a stolen suitcase alarm?".

A few months ago my wife bought me a digital camera so I am now able to illustrated the hundreds of constructional projects on the homepage. The latest is an all CMOS 4000 series (3 chip) frequency synthesiser which can cover about 6Hz to 4MHz. There is also a 0.75uV PD sensitivity FM band receiver and even technical data on the ZN414 and ZN416 ICs (in PDF format). The URL? Sorry! There are three:

http://hem2.passagen.se/sm0vpo
http://members.xoom.com/sm0vpo
http://www.geocities.com/SiliconValley/3569/

I hope shortly to introduce a kit of parts for the TDA7000 receiver (no coils required) as well as to be able to supply a PCB artwork ready for making the PCB, in exactly the same way as the FM Wireless Microphone project. I'm working on it.

Will post another update when the next few projects are added.

Best regards Harry, SM0VPO

5956. Re: Elecrolytic capacitor labeling?????

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-20 00:00:00 UTC

To check polarity, connect DC ohmeter across electrolytic capacitor.
When the positive ohmeter lead is connected to the positive capacitor
terminal it will charge up very much faster. If its the wrong way
round, the leakage current will prevent the capacitor from becoming
fully charged.

And make sure that the positive ohmeter lead really is the positive
side of the internal battery by using a seperate voltmeter.

OR just connect a 1.5 to 9 volt battery in series with a high
resistance voltmeter and observe what happens on the meter. DON'T
use a milliameter to do this test.

From: Peter Lawton <peter_john.lawton@virgin.net>
Message-ID: <367D5518.6870@virgin.net>
Source record: 75580

Any one care to put me in the picture about oscillator phase noise?
One gathers that it is a very important feature of a first oscillator,
but I have no idea what causes it.
Thanks
Peter Lawton G7IXH

5959. 2N5160 2N3866 SPICE model and parts

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-20 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <367D57CC.C1B96235@lafn.org>
Source record: 75581

Hi,

Does anyone know where I can buy 2N5160 2N3866 transistors (small
quantity)??

Also, I really need the SPICE models for
1 watt 2N4427(NPN), 2N5160(PNP) and 2N3866 (NPN) parts.
Only possible source found by web search so far in USA is TECHSONICS
near Foster City, CALIF.

These parts are needed for a 1-50 mhz, 5 v into 50 ohm load, sinewave
power amp using PNP and NPN complementary driver transistors.
I am working on with Winspice3.

Thanks so much for any help.

Those are OLD parts ... they were in common usage back in 1970
when I first started working as an RF design engineer ... no wonder
they are getting hard to find.

There are many modern parts which would provide better
performance in virtually any application ... I suggest you check
out some of the RF transistor manufacturer's pages ... like
Motorola, Siemens, Philips, and others ... and select more
modern, readily-available parts.

Actually, the ARRL Handbook has a reasonably good, easy to
understand, tutorial on phase noise in its section on oscillators.

No, not really. I am not much concerned about QRT at all, and I do not
see why the R2/T2 project should be regarded as for QRT
My main interest is VHF/UHF and microwave technique, and a thought was
if this is suitable with transverters. I plan to use S53MV DC SSB
transceiver for 23cm, but dynamic range is not too good for the lower
frequencies. Some need exists to improve 80/40m receiption, particularly
with serious intermodulation problem on 40m band.

Peter
The PLL only has a lock range of 5-10 KHz. I think the original design
there was a push button the lock and unlock the VFO. The main VFO tuning
is independent of the PLL ie a Variable capacitor etc.The circuit was
designed to stabilize a free running VFO by Eamon Skelton

I don't know if you can assume that or not. Maybe somebody is making alumina insulators. If they're thin enough, they might be adequate for undemanding applications. (For example, you might have an application where the voltage is very high but the transistor dissipation isn't, where alumina might make sense. I hadn't heard of an alumia insulator, but then I've never encountered an application like this.) With the 10:1 or so difference in thermal resistance, it would be easy enough to compare two washers and determine if they're both the same, or one alumina and the other beryllia. If you or anyone else finds out for sure, I'd like to know.

You might try substituting the newer 2N5109 or 2N5943 which are
similar to 2N3866.

>>
>>Also, I really need the SPICE models for
>>1 watt 2N4427(NPN), 2N5160(PNP) and 2N3866 (NPN) parts.

Don't have a spice model for you, but I can tell you that
the most interesting thing about the 2N3866 is the very low
base spreading resistance. That truly is what made it famous.
The reason that is of interest is that you can get low noise
figure with a 50 ohm source impedance.

When I worked for Konel in the mid 70's, they had a VHF marine
radio design done in the early 70's that used 2N4427 transistors
for drivers for the 25W output stage. I might still have some
in my junk box; if you are really desperate let me know and I
can look.

You need to understand that all of these antique transistors used
rather coarse design rules (10 microns or more) and newer parts
made with 1 micron design rules are going to be considerably better,
so you should really ask yourself why you aren't using the newer
parts.

>>Only possible source found by web search so far in USA is TECHSONICS

These "alumina" insulators were quite thick, probably close to 1 mm.
They were the same apparent thickness as the BeO insulators in the
other shapes. And, like the BeO ones, they felt "cold" even through
the plastic bags they were packed in, indicating a good heat conductor.

Wobulator, cor that takes me back. A Wobulator is a swept frequency oscillator. Use of such will allow the alignment of bandpass filters to be observed.

Don

Why not use two AD9850s (or 51s now - with the PLL clock multiplier)
with a common clock and one set for 90 degree phase offset and you wouldnt
need any phase shift networks?
I am interested in trying this - has anyone done it?
Also I presume you can drive a diode mixer direct from these chips.
I would be interested to know how you drove the AD9850 from a software
point of view also

>capacitors in between each switch. Regards!

One way to do it is to use relays instead of switches. Some relays are
rated for SWR and isolation vs frequency; some of the small relays (I'm
particularly thinking of some Omron SMT parts at the moment, but
I'm sure they aren't unique) will cover through the cell phone band nicely.

Cheers,
Tom

I said no further communication and I meant it. Oh
well. Guess you better start filing an action in small
claims court. You waited six months during which
time you never said you wanted the antenna after
I told you to tell me when you wanted it and I would
get it down. Then, you apparently either got a better
deal on another antenna or simply decided you didn't
want mine. During that time my antenna was off
```

the market so I'm out the interest on my money for
those months as well. If you weren't such a jerk
we could have settled this without a problem but
since you chose not to do so then you'll just have to
bear the consequences.
No further correspondence from you will be read.
Merry Xmas
Tony N7BG

5992. RTTY/FEC Decoder Source wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-21 00:00:00 UTC
From: richard.whitcombe@BTInternet.com
Message-ID: <367d9a64.33134201@news.btinternet.com>
Source record: 75608

Hi,
Im looking for source code for a simple RTTY,FEC or other "simple"
digital mode decoder. Mainly i am trying to see exactly how these
things can be done. I did have a simple FEC decoder listing a while
back but was lost in HDD fail a few months back.
I am particulary interested in the ones using the "Hamcom" type of
simple comparator interface. Any language accepted as im aftr a
general overview (C,Pascal,Basic!!)

TIA

Build a Red Box!

If you've ever made a call from a pay phone and put in real quarters (heaven forbid) sometimes you may have heard a series of chirping noises in the back-
ground, really faint. Those are the tones that a pay phone hears when you deposit money and there's a lot of ways that you can immitate these tones to get free calls. This file will hopefully cover every known way to accomplish this. If I've left anything out, get in touch!

5999. Resonant Choke Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-21 00:00:00 UTC
From: cd <bearl@ozemail.com.au>
Message-ID: <75l5vj$8vt$1@reader1.reader.news.ozemail.net>
Source record: 75615

I would like to build a resonant choke power supply. I need complete design information or procedure.
I have searched numerous books, and all i get is a brief introduction with little information.

What i need is the following,

how to calculate the minimum L
how to calculate the resonant freq
the voltage rating of the c
the approx output voltage
the minimum bleeder
the resistance of the choke
the secondary voltage of the primary of the transformer

etc etc

Since many new designers will not be familiar with this technique, probaly many will not know this(like myself)
The Handbook arrl is not much good, in many ways it is not much more than a dictionary.

Anyway hop you can help, please dont tell me to go to Peter Dahl and order it!

Craig

Terry,

My first thought concerning your requirement of 60 amps at 50 volts is your power supply should be a switchmode unit. Linear supplies for that voltage and current would be quite big, with more pass transistors than you could shake a stick at.

My experience with 24v and 48v supplies (from 12 to 100 A) reveals they are all switchmode, even the ones with ferroresonant regulation as well. The ferroresonant units are very heavy, while the straight switchmode are relatively light and small. I don't have any plans for the construction of such a supply, but I'm wondering if the ARRL handbook might have one?

Peter
Phase noise can be thought of as frequency modulation of the oscillator carrier by a noise signal (no doubt the professionals will correct me here) There is also an amplitude modulation component but this is insignificant in most cases. The phase noise has maximum amplitude close in to the carrier and falls off (?exponentially) with frequency offset from the carrier. Poor phase noise performance in a receiver local oscillator will limit the receiver sensitivity due to intermixing with adjacent signals.

I've use a simple broadband termination technique (I'm not the
originator)
to provide constant broadband 50 Ohm source/loads to interstage BPFs.

See http://www.imaxx.net/~kd9jq/diplexer.html for design info. This may
help you out.

How long did you expect to have that amateur license? I suppose if one were intent on doing this, they might get some ideas from the 28 mhz to 220 mhz linear transverter project from the 1994 ARRL Handbook. It may be included in later editions, too. Then, one would have to wonder if the channelized frequencies available on CBs could be converted to match the military bandplan.

From: Don <bjmcpher@usit.net>
Message-ID: <367E9285.6F2EB4EB@usit.net>
Source record: 75626

I did this a few years ago on a 2500 V supply. If I remember right,
there was some info in an old radio handbook or text, probably terman.
But it didnt go into the great detail that you are looking for. There
might have been some equations and charts that were usefull, I just dont
remember. If you dont get any good info, email me and I will try to
retrace my steps and find what I can.

What are you doing? I assume you want to try for the best regulation and
filtering you can achieve, but minimize the size and weight of the
inductive devices?

If my memory serves me, it did work, but I didnt get the performance
that the theory predicted. I may not have had optimum values. I was,
however, satisfied with it. It operated for about a week and the
transformer blew. (not because of the filter, but because I was trying
to milk more out of the transformer than it could handle!)

I put a few answers below, but they are just from foggy memory and
guesses.

Don

Its a function of your minimum current draw. Otherwise, the larger the
better as long as resistance isnt increased.
> how to calculate the resonant freq
120 Hz, or twice the supply freq, for single phase.
> the voltage rating of the c
> the approx output voltage
same as for inductive input filter (i forget the equation)

> the minimum bleeder
depends on how much juice you want to waste, and the tradeoff with
inductor size.
> the resistance of the choke
This, too is a tradeoff. You need it low enought to get a decent Q for
ripple rejection, and good voltage regulation.

> the secondary voltage of the primary of the transformer
determine the same way as for regular inductor input supply.
>
> etc etc
>
> Since many new designers will not be familiar with this technique, probaly
> many will not know this(like myself)

I viewed this configuration as the same as an inductor input supply
filter, but with increased ripple rejection since the series inductor is
tuned to the ripple frequency. I did it because the inductors I had were
not large enought to give me what I wanted, but it is a kludgey way to
do it. The downside is that if you have fixed inductors, you have to
find the proper values of capacitors. In a manufacturing situation its
not bad, since you can design the inductor to what is needed, but I had
to use combinations of several caps to get the resonant freq just right.

> The Handbook arrl is not much good, in many ways it is not much more than a
> dictionary.

I agree. I think everybody should get one every 5 years, but if thats
the only text you need, you arent doing much homebrewing! :)

Hi Richard OM,

I used an Analog Devices AD9850 evaluation board, which is controlled
from the PC via the parallel port. I had obtained this for a project at
work, so it was conveniently available (ie, for free) for tinkering with
the R2.
After using it both ways, I personally do not care for PC control of
frequency. I much prefer a rotary encoder (ie, a KNOB) for controlling
frequency, and elimination of the PC entirely. This I have not done yet
with the AD9850 LO, and I tend to use the analog VFO I built instead,
which is very user-friendly. I am looking for an easy (ie, one I do not
have to invent from scratch) solution to the rotary encoder-to-AD985X
problem.
I added about 12 dB of amp gain after the AD9850, to get up to the
+7 to +10 dBm level to drive the balanced mixers via the RF phase
shifter. However, I did not use any filtering of the AD9850 output,
but I think in general it is a good idea.
Others have mentioned the possibility of using two DDS chips, running
90 deg out of phase for a wideband I and Q output LO. Would like to
tinker with this idea too, but first priority right now is to get my
station up and running again at my new QTH, HI.

As others have noted, a primitive swept-frequency RF source. Particularly cool was the method used to obtain
sweeping action: a motor coupled to the tuning cap, which had no end stops, so, continuously varying frequencies as the cap spun.

Why is squarewave better? Seems to me it's just that many more frequencies fed into the stew. I'm also hoping you're going to tell me they're fed into the DBM at levels far below saturation.

I agree a rotary encoder is the way to go - where can I get one at
reasonable cost?
I think it is possible to use a disk drive stepper motor in reverese with
some electronics to shape the output

> Others have mentioned the possibility of using two DDS chips, running
> 90 deg out of phase for a wideband I and Q output LO.

I have just about finished a board for a single DDS which I will have
professionally assembled (I cant solder those SSOP chips!). If I can get it
to go will consider a quadrature version - could be a while away however
due to time pressures.

The idea is actually to *switch* the diodes with the LO ... most
diode double-balanced mixers want an LO level of +7 dBm ...
"high level" mixers (for higher IP2 and IP3) want +17 dBm or
even more LO drive.

Hello--
I recall seeing another wobbulator variant-- a loudspeaker-like device
with a variable capacitor plate attached to where the cone would go.

And, an electronic version: the Increductor, which used a modulator coil
to alter the properties of a tuning inductor. Kaye Elemetrics used
these in certain sweep generators.

>[stuff deleted]

I've not gotten around to trying it, but the idea of a stepper motor is interesting. There was an article about the idea of using a stepper motor as a rotary encoder in Radio Electronics (perhaps it had changed it's name to Electronics Now at that point) in the early '90s and my memory tells me it was a December issue. I've got it somewhere around, but it would be virtually impossible to locate.

The idea was to simply put a knob on the shafter of the stepper. The finer the steps, the finer the encoding. The author ran the output of the stepper to a pair of comparators; I don't recall any special requirements. The outputs of the comparators are your digital outputs.

The Radio Electronics article was the only place I've seen the idea, though I admit I'm not reading any professional magazines these days. It seems like an idea that would be helpful to many. There was once an article in Ham Radio about making an encoder, and making the disk seemed beyond me.

It's not a knob, but mice and trackballs for computers also have slotted disks that should provide two outputs 90 degrees apart, and cheap mice are certainly plentiful.

With Respect;

You need not use a variable inductor or capacitor to build a wobbulator
(= sweep oscillator) or even a VFO.
See ART 7*, fig 45 pg 149: GW3JNA VCO based on 'turns' cancellation.
This is fb for low frequencies where variable capacitors would be rather
large, but I have also tested in on VHF in a 70MHz FM TV modulator

*Amateur Radio Techniques, G3VA, RSGB 1978 - it is based on comments
from 'technical topics' with some additonal information, it is probably
one of the best books for experimenters, a later book (but different) in
this series is the "Technical topics scrapbook".

The latest RadCom (RSGB) has a DDS project by G3XJP.
He used an AD9850, PIC16C84 and a home brew rotary
encoder.

Go to the AMSAT homepage. Think it is amsat.org.
Look for the files section. In it there is a program called
FODTRACK. The program is a nofriles program, but it has a great
cheep interface that works off the parallel port to control your
rotators. It will also contro the frequency of certain radios.
I have one of the fodtrack setups and it works great. Usually run
it under windows 3.11 and have another program going at the same
time to really see where the birds are.

There are also some other programs there, but I have not tried
them. One of them is suspose to use the same interface but don't
remember which one.

> Mike
snip

I've never had any luck. TDR is a broadband time domain measurement
while swr is a narrow band frequency domain measurement. All the info
is there and can theoretically be converted with a FFT, but the accuracy
requirements make it impractical for most affordable measurement
equipment.
If you try to use TDR to measure the SWR of an antenna, you'll be
disappointed.
But you can use TDR to find opens/shorts or mashed places in cables with
great accuracy. You can TDR the wire to a wall-wart and learn whether
the open is at the plug or at the transformer end. Ditto for microphone
cables etc. You can measure resistor, capacitor and inductor values.
This is particularly useful for determining the tiny parasitic RLC of
components and interconnects.
TDR is a handy device, but not a replacement for an SWR bridge.

FREED TRANSFORMER
115v in for 10.8kv out center tapped at 110mA.
transformer is new, grade 1 military unit from radar rebuild kit.
weight is aprox 56 pounds. 60's vintage, oil filled, never used.
interested? go to ebay and search under TRANSFORMER, unit should turn up in
search.
thanks
HAPPY HOLIDAYS

Downeast Microwave sells the stuff, but it's not cheap.

Rogers is the best-known manufacturer, and is fairly liberal with samples
if you know how to ask. be advised that the stuff is on the
Controlled Munitions list, so exporting the stuff (or things made from it)
outside the U.S is potentially a problem.

N6OTQ

Oh yeah, if you've actually LOOKED at the wide range of stuff on the
Controlled Munitions list, you've probably been as puzzled or amusd
as me. A trip to Computers-r-Us followed by a trip to France could
literally earn you a death sentence.

So, this is a 7904A? The 7904 is not 500MHz, it's somewhat less. This looks like a very good deal, BTW, even if it is a non-A 'frame. The non-A has somewhere in the vicinity of 400MHz BW, I think.

See http://www.caip.rutgers.edu/~kahrs/testeq/7000.html for lots of useful info on these wonderful scopes.

The 7904 is indeed 500Mhz, if some don't go out to 500, the vertical amp has probably been overcompensted. Tek speced them at 500 Mhz and mine has tested easily at that.

Hi Gang,
I'd like to experiment some circuits of product detector with beam
deflection tubes
like 7360 and/or 6AR8.
I need to know the suggested values relatively to dynamic characteristics,
for example: what about max input signal for better IMD? What about BFO
signal? I think not more than 15/20 Vpp....
Thank you.
Merry Christmas and Happy New Year to all.

Claudio

Don - W6JL and a few others have been asking about a 9850 DDS VFO
that they can control with a knob. I already designed just such
a beast using the Greyhill opticaly encoded "knobs" It uses the
Motzorolla 68hc05J1a and displays on an LCD screen. If enough
people are interested please send me an E-mail with what you
would like to see in a 2nd generation DigiVFO and maybe I'll
make a few extra PCBs. The one I built for myself uses one of
those 125MHz "pods" so you can't trim it. Problem? I don't get
a lot of drive from the output but for most purposes? The
filtering of the output is?? I don't have the equipment to
really do that right. I'm interested in a complete transcev
project but my talents are... lacking. Anyone want to combine
efforts? 73 - Jay W0VNE

p.s. I'm also that guy who has the bulk purchase deal for Circad
http://www.holophase.com Check out the free demo you can build
stuff with it! In short I order enough Circads every year to get
one hell of a price. If you want to get in on the deal all you
have to have is a Ham ticket and be in the CD callbook. E-Mail
me if you want one for less than 1/3rd the price. *Note I'm
jaded on how good I think Circad is. Try it yourself don't
listen to me <grin>

wobbulator is wellknown in the countries using German instruments, some
other German words are Pegelmesser (Level meter) and Pegelsender
(Precise signal generator), usually the output level is in Neper, dBm,
dBU (0.775V) in selectable impedances of 75, 120, 150, 300, 600 ohm

I believe Philips used the term "wobbulator" for some AM IF sweep
equipment, I bought one just for fun at last vintage auction in Oslo.

Some old circuits used motor to rotate a capacitor (SCR-522), also used
some German Pegelsichtgeraete - one sweeping audio frequencies, and
another sweeping 10-1000kc/s in slow motion with oscilloscope screen

: As others have noted, a primitive swept-frequency RF source. Particularly
: cool was the method used to obtain
: sweeping action: a motor coupled to the tuning cap, which had no end
: stops, so, continuously varying frequencies as the cap spun.

With Respect;

Wobulators could have all sorts of variable L or C devices. One of the earliest was a downlooking FM radar (WWII) used as a (low altitude) altimeter, worked around 70cm but I cannot remember the designation. This used a "loudspeaker" type of variable capacitor. The Rohde & Schwarz Polyskop used a variable permittivity (sp?) "swept" by a magnetic field. Modern microwave swept sources use a similar technique (called a YIG oscillator). Mechanical or electronic variable frequency determining devices in an oscillator constitute a "Wobulator!"

Merry Xmas

I've been asked to post a notice about Circad on USENET by some folks who bought it after hearing about a "discount" on the QRP newsgroup. First Circad is a program for drawing schematics and laying out PCBs. On one cd you get DOS, NT, Win95/98. It is (my opinion) pretty neat and does the job better than any of the other programs I've seen. *NOTE I'm 100% jaded! The author is a fellow I've known for decades. I helped do 0.1% of the program. Ok, so the word is Try it yourself and make up your own mind http://www.holophase.com The demo will let you build little boards. So get that even if you have no interest in buying it. More and more folks send Circad files back and forth and with this you can see whats going on. What is the "discount" I buy a lot of Circads each year. I pay $295 a copy and I resell it to Hams (only) who are listed in the Callbook for $299 295+Postage. The regular price is $1000.00 You don't get phone support through Holophase. You can call / Email me and if I don't know I will call them. You get free updates for 1 year over the web. After that (call me for details) p.s. Sorry for the semi Advert. - 73 - Jay W0VNE

Perhaps I was misinformed; in any case, I didn't mean to attack the poster or his sale price, just to clarify. As I said, I think the price quoted is a great deal whether it's a 7904 or a 7904A.

While I'm waiting for an SWR/wattmeter kit to arrive in the mail, I'm wondering if an oscilloscope can be used as a TDR (time domain reflectometer) to measure SWR. It seems to me that it would be possible, but I've never heard anyone discuss using that method for amateur radio. Any experience, or thoughts on that?
Thanks

Jesse

There used to be a mailig list, but it has either died
or I somehow dropped from it.

ARD is one of the few CAD programs I had no trouble to install.

I did it yrs ago. As I recall, measured L of choke, calculated C, then
tweaked C for max DC volts out.
It's still working.
It's 2500V at 500ma. Use the amp tubes at 80ma for bleeder.

I did see an article in one of the ham mags describing how to build a
TDR circuit to use with your oscilloscope. I don't know which mag. but
if you posted the question, I think someone would know.
But can you tell me how a TDR is used to measure SWR.

Thanks Bill,

I called ARRL and they say that this is a known problem, but with no known solution. The "hang" that I described, just happens on some computers. On other hardware identical computers it does not happen. It is known to happen on a variety of computers. My particular "hang" (there seem to be others) is identified by the presence of a 2 pixel thick insertion point cursor in the status bar near the lower left hand corner of the screen. This problem does not seem to happen on Win3.1, only on Win95 machines(but not all Win95 machines by far).

I have resolved my problem by installing the software on a different Win95 computer.

High-end commercial TDRs (I'm talking many thousands of dollars here)
can give read outs in "return loss", which can be converted to VSWR by
formula or table. A wattmeter/bridge is easier to use and much-much
more affordable.

I'm interested in homebrewing a modest 75-meter, AM tube type transmitter (really, I'd prefer to build a transceiver) - maybe 20 watts or so.

Don't know much about homebrewing but am interested in learning. At this point, I don't think I could (or would want to) design a radio from scratch - but building someone else's (proven) design is certainly doable. Maybe this is too big of a project for an almost-first-timer, but I'd like to have a go at it anyway...

Can someone point me to books, etc. with designs for such a beast?

Preferably books that are currently available as I don't have any old handbooks, etc. where those designs were probably more prevalent. Of course, good web sites are always welcome - but I've surfed far and wide without turning up anything truly useful...

I agree with the question of detents. I like the "feel" of the greyhill knob that I used in my DigiBrain VFO and the new improved 9850 SuperDigiBrain. It has rubbery clicks so that once set it stays put. To me it feels like one of those very nice German Car radio knobs. Other like the freewheeling give it a spin feel. Oh well to each his own.

Hi Robert,

My exposure to Scintillation counters goes back to 1960's when they were used with a scintillation detector (Sodium Iodide crystals/photo multiplier tube/ columnator) used to detect radioactive events, such as isotopic identification and relative activity.

At that time I was employed by Radiation Instrument Development Laboratories as a tech-writer. RIDL was a manufacturer of physical science equipment which was eventually absorbed after many mergers by Siemens (current manufatureres of MRI systems for the medical field. I have been away from the physical science field since 1970, but will be happy to relate any specific pertinent information to which I am privey.

I also thought that an analog tuning knob was a must when I was building my DDS VFO. I got lucky in that I was tearing apart an old electronic bathroom scales (maybe looking for a strain guage?) at the time and found that it contained an optical wheel and pair of LED/photodetectors in the same housing. I was able to mount the thing on a 1/4 inch shaft and come up with a circuit using a couple of flip-flops to detect pulses and direction of rotation. It worked great.

So ... get your crowbar and head for the bathroom.

Marty, what your really need to do is to attend a few hamfests, or
prefferably ham swap meets, and pick up some old arrl handbooks from
the 60's and maybe even early 70's. They will be cheap, and they
usually have several designs which are pretty well proven. These
construction articles are so complete that they make a very good
starting point for a beginner.

Message-ID: <36816E30.B095F1E3@buffnet.net>
Source record: 75539

Builders,

I have a quantity of new old stock of RCA N-dual gate fets RCA part number 40673.
These were commonly used in equipment described in QST, ARRL handbook, Solid State Design for the Radio Amateur, Radio Handbook and many other publications. They are used in rf amps,/pre-amps, mixers,if amps,etc. They were frequently used in receivers,qrp equipment and receive converters. They may have been used in the heath HW7 or one of the mods.

There are some subs used with varying degrees of success. These are original RCA stock.
**
The current RF parts price on these items is $6.95 each plus shipping after you meet their minimum order.
**

These were purchased as part of a group purchase at a significant savings and are available for $3.50 each. I purchased a larger quantity than needed to get the price. You may benefit and get them at the same price. Tell me how many you need. Add one dollar for shipping (for a padded mailer/postage)

Happy holidays

A very good friend needs one for some half-wit military resurection project.

I'd be willing to pay a lot, say $12 plus shipping, for one of these.

And for the puzzled readers a dynamotor is a combo dynamo-motor.

You put in, say, 12V @ amp.s to run the motor & out comes, say, 300V @ itsy current to run tubes. They sound like hair dryers when running.

They're not as practical as hair dryers.

Thanks,

Marty (marty@aa4rm.ba-watch.org)

Hi,

Does anyone know, how to receive Subsidiary Communications Multiplex Operation (SCMO) channels with minimal component. It's like FM.

I like to build a receiver which could be operated with low voltage like 1.5 V AA batteries. And I don't want to include an amplifier with it. I just want to build the basic signal decoder and then want to use an existing amplifier to hear the broadcast.

Could some one help me....Please.... if you have any basic diagram or any information would you please send.

Thank you in advance.

Jude

Hello--

For what it's worth, my copy of the Telefunken Laborbuch (dated 1958) includes a circuit for a "wobbler" for 10.7 MHz on page 224. The circuit consists of an oscillator stage and reactance modulator (both implemented with type EF800 tubes).

Even though I don't speak or read German, I consider this nifty little blue book a worthy companion to RDH4.

>So, this is a 7904A? The 7904 is not 500MHz, it's somewhat less.

This is not correct. Both models have 500MHz bandwidth. The 7904A chassis has the separate "acquisition" and "display" modules and a different front panel layout, but otherwise there is not much difference to the user.

It's hard to say which is preferable -- 7904As are newer and likely to be in better condition, but it's probably easier to get parts for the 7904 since there are more scrap units out there.

Yep...free is good.
1/2 price ain't too shabby neither. :-))

Ft-1000d is better that heath kit etc etc etc.

It is still fun to build simple circuits even without engineering
background.

The point of the post is to make parts available at a discounted price to anyone that may be interested. Whether it be builders, experimenters or nostalgia buffs or collectors or whatever you want to call it.

People are even restoring tube rigs.....go figure. :-)

Happy holidays to all.

Bill.....I've had trouble along this same line and it was due to moisture inside the cable jacket migrating into the insulation between each conductor. Most of the rotor cable I've seen lately is pretty flimsy stuff, made of poor quality copper and even worse insulation. Many arent aware of the fact that PVC insulation can have bunches of pinholes in it, causing leakage paths to ground, should the cable be shielded, or between conductors in a multi wire cable. I spent some years repairing cable for one of the Bell companys, and this is a common problem with buried cable.

Look for a low spot in your cable and see if water has collected there. A good way to find it is to run your hand over the suspect location and watch the resistance change between wires.

Good Luck...

6099. High Impedance Probe circuit in QST? CQ? 73?

Newsgroup: rec.radio.amateur.homebrew

A few months ago, a circuit for a high impedance probe (for use with a spectrum analyzer) appeared in one of the above magazines. I meant to buy the mag, but it vanished before I got around to it.

As I recall, it used a FET input and an MMIC device for lo-Z out. I'd appreciate it someone could tell where the circuit appeared, and if I can find it on the Net. Any information most appreciated.

I'd like to use the cct to couple my HP-312A into a Singer MF-5/CA-5-1 (SSB-50), among other things.

TIA

Don't see the reason for European QRP enthusiasts to buy the much more expensive Motorola transistor when a Pro-Electron consumer device is readily available at very low price in almost every electronic shops.

MRF476 15-18dB gain 3W RF on 30MHz, and I measured a common collector PA using 4x BD139 to 15dB on 28MHz (10W RF). Case TO-220.

BD135 BVCE0 45V, BD137 - 60V, BD139 - 80V, NPN 1.5A 10W,
HFE 40-160(250), TO126

I am quite aware that some small switching FETs may be better for some applications today, but still, quite frequently MRF476 seems required

Marty, Don was correct. You could also check into ebay auction site as they have tons of old ARRL handbooks that have good AM transmitter projects. I recommend 1955 and earlier although pre-war (II) might be a bit much for you. I would not tackle the receiver until you have a good solid foundation in building tube rigs. Finding parts is not a problem and should not detract from your decision to build a rig. If you get real serious and need help give me a buzz--I build a lot of equipment and have since 1955. Source record: 75479

I found this 16 el. 2-meter antenna in a magazine called "Out of thin
air.."
published by PW in 1981.
This antenna is supposed to give a measured 16dBd gain on a 426cm long
boom.
The secret is said to be in the two driven elements (ZL special) that
will give almost
4dB of extra gain. Can this be true?

If so, this must be the best performing Yagi antenna ever.

If it really works that way, I will build a couple of these antennas in
a hurry, but
why is this type of antenna not mentioned anywhere else?
That makes me a bit suspicius.

I disagree Harold A simple AM transmitter is an ideal project for a
newcomer to the solder melting arts.

I agree that new builders shouldn't tackle receivers until they have a
couple of transmitter projects under their belts. But even simple
receivers are do-able for homebrewers. I'm listening to my HB Mighty
Midget receiver (3885 AM) right now.

Hombrewing from scratch is one of the best parts of ham radio. And
it is not hard to find parts. In fact, with the advent of FEDEX, UPS
and the internet, it has never been easier to get parts (delivered to
your door the next day!)

As for kits, I know this is a sensitive subject, but having built both
kits and HB projects, I've concluded that the real fun is in
"building from scratch" HB.

I hope Sant left many soldering irons and new 6146s under the trees
this year!

Merry Christmas to all!

You can build one or buy one! (Comet and Diamond both sell one).
LP filter on VHF side with cutoff around 160 MHz.....HP on the
220 side with cutoff around 210 MHz.....depends on how much
loss you are willing to live with and how much isolation you need.
(the Comet/Diamonds have 45db+ isolation and about .3db loss...more
than enough!)

I have 80+ of these relays. They are 24 volts dc, rf relays. THey have good performance up to about 1 GHz. They are douple pole double throw. I've used them in RF attenuator circuits, where you either switch thru or thru a pad using only one relay. They take about 20 watts at the low frequencies. They can also be used to switch in delay lines etc.

Price is 3 for $10
10 relays for $25
25 relays for $40
80 relays for $100

indeed, several German books were available free or at low cost for
radio-amateurs. For several years I received the annual
"Siemens Halbleiterbeispiele". Also Telefunken 'Taschenbuch' 1967
(Pocketbook - R&#65533;hren, Halbleiter, Bauteile) is very useful containing
100pages Radio/TV design/repair information. and several hundred pages
of detailed information on valves and semiconductors. Philips also had
some pocket books, easy to find, but usually valve data was only 4-5
lines, not much useful..... But around 1970 and onwards Motorola
parts became the easiest semiconductors to buy for hams here, and very
much application notes were available free of charge(?)

6120. How to connect Line In to ICom 740

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-25 00:00:00 UTC
From: Bob Sikes <rwsikes@mediaone.net>
Message-ID: <3684169A.BA086D47@mediaone.net>
Source record: 75492

Hi,

I hope this is an appropriate topic for this board. It's at least half home brew I think.

I have an ICom 740 which requires a preamp mike and puts 8V DC out on the mike input pin. And it doesn't seem to have a input pin for line level in. I'd like to couple the line out of my sound card to the rig for a couple of reasons. I'd like to use it to send out AFSK and perhaps MCW. Also, I have a crazy idea about sending the audio from my computer mike, using voice recognition and voice command for logging during contesting.

I've tried the obvious, just hooking up to the correct pins, capacitive coupled to block the D.C. But with signal I don't seem to get much of a response from the ICom. It claims that the input level should be at about 120 mV. Well, at 120 mV, there is no output of the transceiver. When I crank up my level to about a Volt, I get some distorted output, not good.

I think I'm probably missing some basic concept. Any thoughts? Has anyone done this with the 740 or a comparable transceiver?

>4dB of extra gain. Can this be true?
>
No. A 2-element ZL Special has gain over a dipole, but that is not true
when replacing a dipole driven element in a yagi.

A ZL Special (2 element log periodic) driven element cell can have a
wider VSWR bandwidth than a dipole drive element, as KLM have shown, but
that has nothing to do with the gain.

>If so, this must be the best performing Yagi antenna ever.
>
>If it really works that way, I will build a couple of these antennas in
>a hurry, but
>why is this type of antenna not mentioned anywhere else?

Simply because it doesn't deliver the claimed performance.

>That makes me a bit suspicius.

Smart guy, Anders!

6123. Sat LNB for 10GHz ATV ???

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-26 00:00:00 UTC
From: Colin Lowe <colinlowe@compuserve.com>
Message-ID: <#MIIApFM#GA.339@nih2naab.prod2.compuserve.com>
Source record: 75495

Hi all, I have a old working Satellite TV LNB and have heard you can convert them for the 10GHz Amateur band. I have a local ATV repeater very close to my QTH and would like to see If I can modify my old LNB for use on 10GHz. The frequency I need it to work on is 10.340GHz. And the LNB is a standard type as found on the UK Astra system.

I look forward to your reply.

73 and Happy Xmas.

6124. Unloaded Q for T50-6 toroidal inductors

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-26 00:00:00 UTC
From: fred@internet_cafe.net
Message-ID: <A8_g2.1596$DC.4439073@newsgate.direct.ca>
Source record: 75496

I would like to know the unloaded Q of (inductor)resonators made from Amidon
T50-6 toroids at the following frequencies. The values are needed
to designing bandpass filters.

3.75 MHz 4.7 microhenries
7.2 MHz 4.2 microhenries
10.293 MHz 2.1 microhenries
14.2 MHz 1.3 microhenries
21.2 MHz 0.8 microhenries

Any help would be appreciated
Thanks Fred

Mastr Pro paper weights? Why should I use expensive II's when the hybrid Pros are dirt cheap and last virtually FOREVER in continuous repeater service. I have a mobile one with a frequency synthesizer (non-GE) add-on in my car as well, and think they're ideal for the budget-conscious ham.

I admit I recently got rid of my Prog-Line collection, so I guess I am modernizing a bit <G>. I had both T-Power and vibrator units, but not the original dynamotor version.

If you guess a value of 200 that will be not far off. Variations from 170 to 230 will not affect the simulations by more than a couple of tenths of a dB. That has been my experience.

: 7.2 MHz 4.2 microhenries
: 10.293 MHz 2.1 microhenries
: 14.2 MHz 1.3 microhenries
: 21.2 MHz 0.8 microhenries

My Q-Curves charts show it only for the following three cases
and I am taking Q at the frequency you want from the graph:

T50-6 25turns #22 = 2.60uH Q = 260 @ 10MHz;
T50-6 19turns #20 = 1.54uH Q = 248 @ 14MHz;
T50-6 14turns #18 = 0.86uH Q = 235 @ 19MHz
extrapolated to be 220 @ 21Mhz

Another catalog I have shows
T50-6 50turns #27 = 10uH Q greater than 200 from 3MHz to over 8 Mhz

I don't know if this is much of a help . . .

6139. Kenwood PB-13 parts

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-26 00:00:00 UTC
From: Joe Kraft <joekraft@csi.com>
Message-ID: <3685AA6C.3648478B@csi.com>
Source record: 75511

I pulled apart my PB-13 battery pack to replace the cells and it has a small (3 mm X 6 mm X 16 mm) white box looking thing with two leads. The box appears to be made out of plastic with a ceramic plug and two leads on one end. The markings on it are (from the end with the leads):
1) A symbol made up of a letter 'M' inside an octagon, I remember seeing it in my college days but don't remember the manufacturer.
2) The letter 'T'
3) 80AR3U2
4) Some letters turned the other way that I can't make out for sure, maybe 17C??

A couple of questions. First of all, what is it? And second, do I need to put it back in when I rebuild the pack? And third, Does it matter where it goes in the pack?

I'm guessing it's some kind of thermal cut out, it was in series between the 4th and 5th cell in the pack and tucked down in the middle of 4 cells.

Thanks for any insight you might have.
Joe. (WL7VC)

6146. Re: Chip cross reference

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-27 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <368659AA.4EE8DB94@mlecmn.net>
Source record: 75320

The summary below is from the QuestLink IC database, which can be found at http://www.questlink.com

Digi-Key carries Maxim ICs, but the MAX639 is not listed in their catalog.

Lyle, K0LR

Here is a summary for the MAX639:

5V/3.3V/3V/Adjustable, High-Efficiency, Low Iq , Step-Down DC-DC Converter

Features
High Efficiency for a Wide Range of Load Currents
10uA Quiescent Current
Output Currents Up to 225mA
Preset or Adjustable Output Voltage:
5.0V (MAX639)
3.3V (MAX640)
3.0V (MAX653)
Low-Battery Detection Comparator
Current-Limiting PFM Control Scheme
Description
The MAX639/MAX640/MAX653 step-down switching regulators
provide high efficiency over a wide range of load currents,
delivering up to 225mA. A current-limiting pulse-frequency-modulated (PFM) control scheme gives the
devices the benefits of pulse-width-modulated (PWM) converters
(high efficiency at heavy loads), while using only 10uA of supply
current (vs. 2mA to 10mA for PWM converters). The result is high
efficiency over a wide range of loads.

The MAX639/MAX640/MAX653 input range is 4V to 11.5V, and
the devices provide lower preset output voltages of 5V, 3.3V, and
3V, respectively. Or, the output can be user-adjusted to any

voltage from 1.3V to the input voltage.

The MAX639/MAX640/MAX653 have an internal 1A power
MOSFET switch, making them ideal for minimum-component,
low-and medium-power APPLICATions. For increased output drive
capability, use the MAX649/MAX651/MAX652 step-down
controllers, which drive an external P-channel FET to deliver up to
5W.

From: Dave Skarbowski <skarbows@ptd.net>
Message-ID: <36866691.71443031@ptd.net>
Source record: 75321

I'd like some comments on a proposed single conversion receiver design:
I'd like to home brew an all band SSB receiver including AM SW that has
single RF stage followed by a mixer and IF amp. The IF amp would then
feed an R2 module (tunable IF/detector). What would be a good IF
frequency for this design? How about AGC? Can audio derived AGC work
as well as RF derived? Would I be better off with a fixed freq IF and
VFO inject the mixer? This would allow me to filter the IF and derive
RF agc. What do you guys think?

Dave, KX3DX

A 40-feet (12 metre) garden is not long enough for a trapped dipole
for 80 and 40 m bands.

So go for a short loaded dipole with long helical loading coils
roughly 2/3rds of way from centre feedpoint to
the ends. Long coils allow large diameter hence low loss wire to be
used. 2-inch dia plastic drain pipe makes fine formers. Disadvantage
- a short antenna will have a narrow bandwidth.

Suggested dimensions : 3.5 metres from dipole centre to inner end
of loading coil. Coil length = 0.5 metres. 2 metres from coil to
end of antenna. Overall length of dipole = 12 metres.

Now comes the awkward bit - how many turns of what gauge wire to
wind on the 50mm diameter drain pipes which will resonate the antenna
to 3.7 MHz. No problem - there's program VERTLOAD available from
my website which is designed to do that tricky job in hardly more
time than it takes to enter the above dimensional details.

VERTLOAD is organised to design loaded verticals in double-quick time
on a ' what-if ' data input basis. So you design a loaded vertical
with an overall height of 6 metres and, Bingo !, put two of them
together back-to-back and you have a 12-metre loaded horizontal
dipole.

Set the ground electrode loss resistance to zero. Dipole feed-point
resistance will be exactly twice the computed vertical's value.
Radiating efficiency will be the same as that of the vertical.

If you are unable to obtain two high supports for the dipole then use
VERTLOAD to design a loaded vertical for whatever height you can
manage, sloping or not. But you will need a good ground connection.

A simple unloaded Inverted-L with a good ground may perform better on
80m than you might expect. It will also perform very well on all
higher frequency bands. No loading makes it multi-band up to 10m
band. Use program ENDFEED to investigate performance of simple
verticals and L's. This program takes the ground electrode system
fully into account. It also computes coil and capacitor values for 3
different antenna tuning/matching networks.

What about a magloop ? Need not be a small circle. Can be a large
rectangular thick wire. While the weather is bad do some armchair
investigating using programs RJELOOP1 and RJELOOP2. All user
friendly ' what-if ? '.

Help yourself to a belated Xmas present by clicking below my
signature.

Sounds as though the height issue should be resolved first. If he can get high enough then an inverted V with doglegged ends may fit ... saves a lot of work, and perform well.

Just a thought ...

I noticed some folks were looking for rotary encoders, perhaps these units would work.

For Sale:

New Hewlett Packard model HRPG-AD32-56R panel mount optical encoder,

1/4 inch shaft (1/2 inch long) with 3/8 inch threaded collar. Electrically the unit generates 128 quadrature steps per revolution, but

is detented at 32 invervals with a guarantee that Phase A and Phase will

not come to simultaneous logic Highs in any detented position. Runs on 5 vdc with connections made via an array of inline pins spaced at 100 mil intervals. Unit can freestand on threaded collar or can be soldered

directly to a pc board via connection pins and a 4 point solderable bracket to add strength to the pc mounting scheme. Full technical data available from the HP web site under components. Great for DDS projects. Metal construction. $10.50 post paid Three Day conus with data. BTW the detent ball can be removed with a carefully drilled hole for 128 unique positions per rev if desired.
Thank you for the read

Bob, KE6F

The only one of these questions I can contribute an answer to is the one regarding audio derived AGC. A natural problem occurs if you have a receiver with any audio filtering within the AGC loop. That is, if there's an audio filter between the stage whose gain is contolled by the AGC and the stage where the contolling signal is sampled, I don't believe you'll be able to get clean AGC action. This is because of the unavoidable delay-phase shift of the filter. The only way I can see to add AGC to a DC receiver is to make the front end of the receiver strong enough to handle the largest signals without AGC, then put an AGC controlled amplifier entirely within a portion of the audio section where the audio bandwidth is wide. If you put audio filtering after the AGC loop, though, then signals which are outside the filter can still dump the gain. These problems might be overcome or alleviated by clever application of digital techniques, but I haven't heard of anyone who has actually made a really clean audio-derived AGC using either analog or digital methods. If anyone knows of one, please post it.

From: littlejohn_1@hotmail.com
Message-ID: <768acs$n3c$1@nnrp1.dejanews.com>
Source record: 75335

Greetings,

I am very interested in RF Amplifier design. What I would like to know is how do you calculate the correct dimentions for tuned input and plate coils? Is there a formula for figuring these? I own a copy of Sams "Radio Handbook" (w6sai) and "The Radio Amateur's Handbook", but neither seems to go into detail on how to calculate the dimentions of the coils. There are several RF Amplifier plans contained in these books which already give the dimentions for the coils, but I wish to understand how the designers calculated these dimentions. Any input would be greatly appreciated.

Thanks,
JW

6163. Re: DC/Hetro receiver design - need comments

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-28 00:00:00 UTC
From: PSK <singhpkxxx@ix.netcom.com>
Message-ID: <3687EC6D.DD969D87@ix.netcom.com>
Source record: 75337

Got my R2 up yesterday atlast.

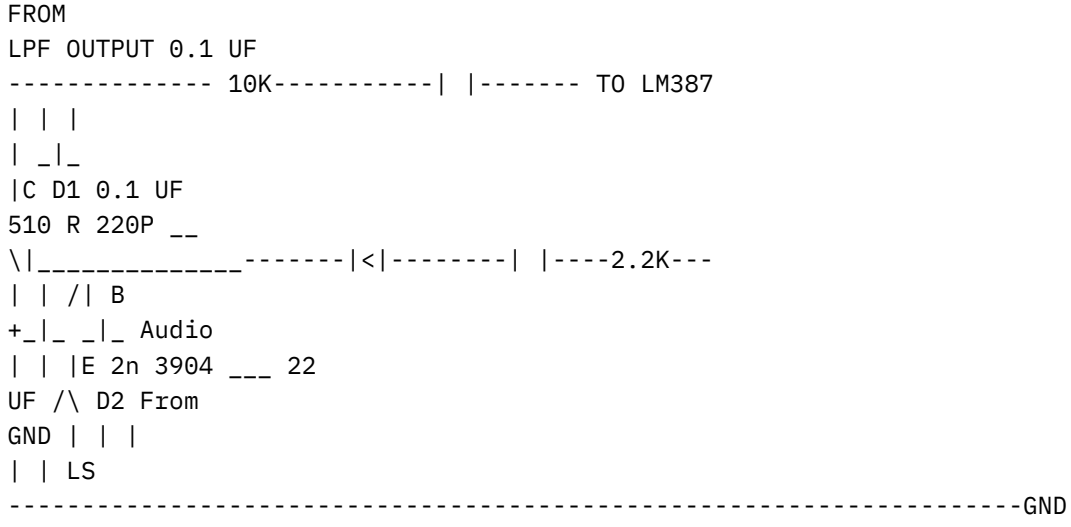
I brewed a simple audio AGC using a bipolar 2n3904 transistor
and a 2-diode (1n4148) charge pump.

The charge pump is fed from the speaker connections of the R2 via a 2.2K
resistor.
The C1/C2 of the charge pump are 22 UF and 0.1 Uf.
The DC output from the 22 UF output capacitor of the charge pump goes across

the B-E of 2n3904. The collector of the 2n3904 is connected across the
input 220 pf
capacitor at the input of LM387.
The 2n 3904 AND THE 10kRESISTOR FORM A RESISTIVE VOLTAGE
DIVIDER LIKE A VOLUME CONTROL , AND THE VOLTAGE ACROSS
THE lOUDSPEAKER IS MAINTAINED AROUND 1.5 v p-p Or so, WHIC IS MORE THAN
ENOUGH AUDIO
FOR LISTENING ON A HEADSET OF ANY KIND.

(PERHAPS SOMEBODY CAN SHED SOME LIGHT AS TO HOW A BIPOLAR TRANSISTOR
CAN WORKS LIKE A RESISTANCE FOR AC AUDIO VOLTAGE !)

The volume control has been removed , as it is no longer needed. Instead
of it, a 510 Ohm resistor
terminates the Low pas filter, and a 10 K resistor couples audio to the
LM387 Input.



THIS CIRCUIT WORKS WELL ENOUGH, THE ONLY DOWNSIDE BEING SOME SLIGHT VISIBLE

FLATTENING OF LARGE AUDIO SIGNAL TOP PORTION FOR STRONG SIGNALS.

I WONDER WHY I HAVENT SEEN THIS SIMPLE AND VERY EFFECTIVE AUDIO AGC CIRCUIT BEING USED MORE OFTEN !

PLEASE POST YOUR THOUGHTS AND EXPERIENCES WITH THIS SIMPLE CIRCUIT .

(note: NEXT PROJECT, TESTING A 50 OHM PIN DIODE ATTENUATOR FOR RF AGC !)

Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.ham-radio,rec.radio.amateur

I have a new Yaesu ft-920 HF+6M radio and have been itching to do the
Tx-expand mod found at various radio mod sites. See:
http://home1.inet.tele.dk/ehh/mods/mod/yaesu/ft-920.htm

This mod involves uploading a file directly through the serial port that will
supposedly unlock Tx on the full range of frequencies.

I have searched around and read the newsgroups and some have said that
this mod was not intended for the US model, and that it could damage the
CPU. Others have said that it worked fine. I did not actually see any posts
from anyone who did the mod unsuccessfully and ruined their radio.

I would appreciate feedback/comments from people who have performed this
mod to their radios, and what the outcome was. I would like to see this issue
clarified once and for all.

Please, no flames.

Thanks,

Hugh

Dear Sirs,

NavigatoR Ltd, a Russian company, specializes in trading
Russian vacuum tubes used for air and marine navigation, radar
as well as in broadcasting, amateur radio, Hi-Fi audio,
meteorology, communication, medical applications and industry.
All tubes are engineered and manufactured in Russia. Tube types

include Broadcasting Tubes, Magnetrons, Travelling Wave Tubes
(TWT), CWT, Transmitting Tubes, Klystrons, Amateur Radio Tubes,

Hi-Fi Audio Tubes, Industrial Tubes, Transmitting Pulse Tubes,
Modulator Tubes, Modulator Pulse Tubes, Control Tubes,
High-Voltage High-Vacuum Rectifier Tubes, Cathode Ray Tubes,
Ceramic Tubes, Diodes, Display Tubes, Electron Tubes, Hydrogen
Thyratrons, Ignitrons, Noise Source Tubes, Nuvistor Tubes,
Pencil Tubes, Pentodes, Photodiodes, Readout Tubes, RF
Amplifier
Tubes, Receiving Tubes, Rectifiers, Vacuum Relays, Spark Gap
Tubes, Subminiature Tubes, Surplus Tubes, Tetrodes, Thyratrons,

Vacuum Capacitors, Vidicons, Voltage Reference Tubes, X-Ray
Tubes, and Glass Tubes.

Russian vacuum tubes have a worldwide reputation for being
highly reliable and unique. A repairs facility is available for

all Russian vacuum tubes and for a wide range of equipment
manufactured by other companies.

Our microwave products for wireless communication systems
are
in great requisition.

Please, check our web-site http://www.tubes.ru/
We accept foreign orders.

Thank you in advanced

Andrey Bodunov
P.O. Box 78, Moscow, 115446, Russia.
Phone/Fax +7-095-1124422
E-mail: contact@tubes.ru

This issue can't be "resolved once and for all". As several previous posts have indicated, the sucess or failure of the mod depends on the CPU version and E-Prom Bios rev in your particular radio. Since there is no info on which versions it will work with and which versions it will destroy, the risk is yours. Take a gamble and try it, or be safe and send it to Yaesu with a copy of your MARS/CAP endorsement and they will do it for you for the cost of shipping.

(Incidentally, I have seen a post or two on the newsgroups from persons who have had damage from trying this mod. You might want to search www.dejanews.com and try to find them for yourself. However, I would suspect that most of the people who may have messed up their rigs with this mod would avoid telling the world about it by posting it here.)

As Mr. Eastwood once said "Do you feel lucky ?"

Its probably not the extra self capacitance that is _causing_ the
decrease in Q. Its more likely that _both_ the extra self capacitance
and the loss in Q depend on another variable, like the shape of the
inductor or length of wire used etc.
Peter Lawton

6176. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>

Source record: 75350

I think it depends on where the capacitance is coming from. Here's a thought experiment.

I have a Q measuring fixture that consists of an air-variable capacitor that I solder the inductor across, and a couple of very small capacitors to couple a signal in and out. I measure the center frequency and 3 dB bandwidth, and calculate the inductor Q from this. An assumption is that the capacitor contributes negligible loss to the circuit, so essentially all the loss is from the inductor.

If I modify the inductor so that its self C increases, I simply reduce the amount of C from the air variable. If the self C is lossless, and if the modification doesn't change the L, the Q will measure just the same, because all I've done is replace some of the low-loss variable C with low-loss self C.

But if the dielectric of the self C is, say, core material and wire insulation, it will add loss to the circuit and lower the Q. I believe this is the reason that increasing the self C will lower the Q.

Most modifications to an inductor that change the self C also change the inductance (not just the apparent inductance, which is the inductance modified by the effect of the self C). If this happens, it could move the Q either way, depending on coil geometry.

Roy Lewallen, W7EL

Could it be that the coil with the greater self capacitance has has more turns on a smaller diameter? This would increase the winding resistance, thus lowering the Q.

Well, for starters there's the inductance required for resonance at the given
frequency with the given circuit elements. Next, there's power-handling
capacity, which is significant at final-amp power levels but is a LOT
higher than you'd think at resonance. Next, there's the required Q, which
is low for an output tank but higher for a tuned input, and usually both
seem to be derived from "duhh, what's Q?"

And of course, there's input and output impedances, which vary dynamically
with voltage and current.

And finally, there's "Well, we've always done it this way."

A good starting point is to look at the plans, look at some working amps,
and use those for a starting point. You can easily estimate inductance
by physically measuring a coil. You can easily estimate working input
and output impedances with a tube's data sheet, and with your design
parameters.

If you have access to a complete set of back issues of "ham radio" magazine,
you'll eventually find everything you need in there. There are other sources,
but don't look to the ARRL to publish a complete, concise guide any time soon.
The best they will do is to publish some incomplete plans that most
amateurs can get to work -- sort of, most of the time.

6183. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <368908BF.E2280177@mlecmn.net>
Source record: 75357

Measurements made on a B&W 3027 inductor (2 inch diameter, 10 inches long, 10 turns per inch of #16 AWG wire) at 2 MHz, using an old Boonton 260-A Q meter. A small air variable was placed in parallel with the inductor. I'm assuming that the losses in the ceramic dielectric of the capacitor body were the same with the plates meshed or unmeshed.

Air variable fully unmeshed:

Q = 428; internal capacitance of Q meter = 60 pF.

Air variable fully meshed:

Q = 332; internal capacitance of Q meter = 46 pF.

The Boonton meter uses a series measuring circuit, in which the Q is given by the ratio of the voltage across the series circuit to the voltage across the internal capacitor when it is tuned to resonance. In this type of circuit, the distributed capacitance of the inductor *does* make a difference in the measured Q.

If the inductor is used in a parallel-tuned circuit, such as a receiving loop antenna, distributed capacitance does not appear to cause a direct reduction in Q; only a reduction in the tuning range. However, when used in a series circuit such as a loading coil on a mobile whip, distributed capacitance in the coil *can* have an adverse effect. A difference in apparent Q, depending on the application, seems to be a paradox. However, it can be verified by calculation (or for lazy people like me, with the help of circuit analysis software).

I guess you have to ask yourself, why do you want to do the mod, and will/can you use it once it's done, and if it works? And remember the old saying... "If it works, don't fix it!" The FT-920 is a super radio... you don't want to screw it up.

Source record: 75359

I was making the assumption that the Q measurements were made at the same frequency. If I correctly understand your posting, yours were made at two different frequencies. For a given inductor, the Q does change with frequency due to several effects. Terman talks about some of these in _Radio Engineering_, and Micrometals publishes a book of curves of Q vs frequency for coils wound on their powdered iron cores. Both show that the Q generally peaks at some frequency and declines on both sides, due to the competing effects which are differing functions of frequency.

6186. KK7B Direct Conversion Receiver - revision?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: owens@ale.atd.ucar.edu
Message-ID: <76bcqt$6c7$1@ncar.ucar.edu>
Source record: 75360

Does anyone know how the KK7B direct conversion receiver kit
is being modified? Please post to this newsgroup if you know what
changes are being made.

Thanks!, CHip, NW0O

Thanks, Lyle, for posting the results of your measurements!

Seems like the bottom line is that you should be sure that you include
the inductance _and_ any important parasitics (resistance and
capacitance) in the model of the circuit where you are actually using
the part. The circuit topology really _can_ make a difference.

I suspect there's also an element of truth in what Roy wrote about the
distributed capacitance in a coil not necessarily being low-loss
capacitance. But I believe there are also effects on the distrubution
of current on the wire caused by the surface of the turns being closer
or farther apart, turn to turn (for the same pitch, because of different
wire diameters). The change in current distribution would change the Q.
(Does Terman have anything to say about this? I'd bet some graduate
students back in the 30's spent months making painstaking measurements
of coil Q versus geometry! :-)

Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.shortwave,uk.radio.amateur

I need to build, buy, borrow or hire a simple valve tester. I've been looking around the Ng's and various sites but don't see a DIY tester and all the FS sets seem to be USA or Canada - unless you know better.

simon.cox@breathe.co.uk

Taunton, Somerset.

I don't have a great number to check so borrowing / begging the use of might be my best option.

6189. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <36893EAA.C6FE9641@mlecmn.net>
Source record: 75413

The measurements I made with the Boonton 260A Q meter were both at 2.0 MHz. The Q meter has an internal air-variable capacitor that is used to resonate the inductor under test. The capacitor is calibrated and has a range of 30 to 460 pF. I left the frequency constant and varied the capacitance setting to peak the output voltmeter, which is calibrated in Q. There are binding posts on the top that let you put external capacitors in parallel with the internal variable. As a cross-check on the losses in the air variable that I was placing in parallel with the inductor, I connected it across the "C" binding posts. There was no noticeable change in Q when the main capacitor was re-peaked.

I'll have to go through the circuit calculations (probably using ARRL Radio Designer or MicroSim DesignLab because I don't trust my arithmetic) to show where the "lost" energy goes, since we haven't changed the losses in the inductor and there are negligible losses in the shunt capacitor I used in the experiment. I've always assumed that the additional loss due to distributed capacitance in a coil is indeed real and is caused by "circulating currents" in the L-C network formed by the inductor and the shunt capacitor. Consider a thought experiment in which we have a mobile whip and a base loading inductor. With no shunt capacitance across the inductor, if there is 1 amp of current in the whip, there is also 1 amp of current in the inductor (at least at the point where they connect). Now put a lossless capacitor in shunt with the loading coil. A smaller inductance can now be used to achieve resonance at a given frequency. If the Q of the inductor (neglecting distributed capacitance effects) remains constant, the series loss resistance in the coil will actually decrease because we've lowered its reactance. However, to get 1 amp into the whip, there will now be *more* than 1 amp in the inductor, and the net (I^2*R) losses in the system will increase. Anyway, that's what I think will happen. Dangerous to make a statement like that on this newsgroup without carefully checking it first, but I'll risk it. Unlike you, Roy, I don't have a reputation to uphold -- and that's meant as a compliment.

6190. Help with SSB RF Sensing

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: ve6inm@my-dejanews.com
Message-ID: <76bkt5$dp8$1@nnrp1.dejanews.com>
Source record: 75414

During this festive holiday season, I have been working on an RF sensing circuit for use with my homebrew 6mx linear. For some reason, I can't seem to get the sensing circuit to work well with a SSB signal. The FM, CW and AM are okay, but SSB is hit and miss. I am coupling low level (7watts) RF thru a 7pf cap and into a 2 diode clipping/rectifier circuit. This is fed to the non-inverting input of an LM-358 op-amp. Also from the non-inverting input, I have a 10k resistor to grd. The output of the op-amp is tied back to the inverting input via a 100k pot to control the gain. Also from the inverting input is a 10k resistor to grd. From the output, the DC is fed thru a 1k resistor into the base of a 2N2222 that has the emitter grded and the collector tied to the negative lead of a 12vdc relay. The other side of the relay is tied to Vcc of 13.6vdc. I have bypassed the circuit with lots of .01 and .1 mfd caps.

The circuit works great and switches just fine with all continuous carrier modes (FM, CW, etc) but when I try to set the gain for SSB input, the circuit either does not switch on or else it causes the relay to "chatter" on and off. A continuous whistle or "hhellllllooooo" switches it OK, but the setting is too damn finicky to trust. If I set the gain a bit higher, the circuit stays held even after the RF is removed from the input.

Any ideas on what I may be able to use to solve the problem. I do have the 'standby' system of using the PTT lead from the rig, but this seems so simple and reduces the wire count.......??

Merry Xmas and all the best is 1999.

Chip- I don't have the URL handy, but try a search for < K0JD, John Seboldt>.
He had a really neat web site with a ton of links to various KK7B receiver projects.
Most of the Mods had to do with the diplexer circuitry and/or improvement in the 50 ohm grounded base bipolar. One of the guys I talk to on 75 meters used an R1 as a 40 meter packet receiver, using a vfo signal tapped off of a JST 245!!!
Good luck with your homebrew efforts in the new year.

Simon,
I have one but I'm in Nort Glos so unless you are passing in the next
few days I doubt if its any use. What comes to mind is that some months
ago I saw an article on constructing a simple valve tester. It was, I
believe, in Radio bygones. If you contact the publisher he can probably
find you the article. They do back numbers for a couple of quid.

If you are passing Stow on The Wold you are quite welcome to drop round
and test any number of valves if this doesn't help.

Regards

Robin

6193. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <36896F00.F7395FFA@mlecmn.net>
Source record: 75417

Here is a follow-up to my earlier posting. I ran some simulations with the MicroSim DesignLab demo software to compare two hypothetical coils. It shouldn't be that hard to do the calculations with pencil and paper, but my complex arithmetic is terribly rusty. So I cheated and used a trial-and-error approach with the simulation software to come up with two coils that have nearly identical properties under some conditions. Coil A has a "real" inductance (measured at some low frequency where distributed capacitance effects are negligible) of 54.28 uH, with a series loss resistance of 5.0 ohms and a lossless distributed capacitance of 5 pF. Coil B has an inductance of 42.5 uH, a series loss resistance of 3.91 ohms, and a lossless distributed capacitance of 15 pF. When measured in Roy's test fixture with a parallel capacitor, I believe each inductor would tune to 3.60 MHz with a 31 pF external capacitor and would show a Q of 246 at that frequency. The apparent inductance would be 63 uH. In a parallel-tuned circuit such as the input of a high-impedance FET preamplifier at a fixed frequency of 3.6 MHz, I don't think there would be any measurable difference in performance between the two inductors.

Now suppose we want to base-load a whip antenna that has a reactance of 1425 ohms at 3.6 MHz. Either coil should tune the whip to resonance at that frequency. However, for a 1-ampere current into the whip, the current in coil A would need to be about 1.16 amps, and the current in coil B would have to be about 1.48 amps. Coil A would dissipate 6.7 watts, and coil B would dissipate 8.6 watts. In this situation, the apparent Q of coil B is lower, even though we have assumed that there are no dielectric losses associated with the distributed capacitance.

In my archives, I found a collectable VOM, that I have no need for.

It is a Triplett 310 "Mighty Mite" VOM. It includes a nice leather case, with Triplett imprinted on it, a set of original probes, and the original manual.

This unit looks as close to new as you would ever find. I have looked all over it and can not even find one scratch. The manual looks new, except for the possibility that the pages are not quite as white as they once were. The leather case is made so that it can go on a belt, but does not look as if it ever was on one.

I have searched the manual, but find no information as to the date it was made. My guess would be in the 50's, but that is only a guess.

$ 75 plus shipping from Florida.

Happy New Year to all.

6198. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-29 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <3689C151.F249A6B4@teleport.com>
Source record: 75422

Thanks very much for taking the time to make the careful measurements. As a consequence of your questions and measurements, I've begun to re-think the basic idea of inductor Q, just what it is, and what it means.

Terman defines inductor Q as the ratio between the reactance and the equivalent series resistance, and that seems as good as any. We have to keep in mind that we're talking about the Q of a real component, which does include some C. To get at Terman's definition, we have to coerce the real component into a model consisting of only two ideal components, an equivalent L and an equivalent R, which are in series. Any change in frequency or in capacitance requires recalculation of these two equivalents, with a corresponding change in Q.

So far I've ground through the equations enough to satisfy myself that a parallel equivalent results in the same Q, given the same L, R, and C. (As a model I've been using an L and R in series, with C across the combination.)

I think the problem is with my Q measurement method. I'm now not sure that the center frequency divided by the bandwidth will necessarily give the inductor Q when capacitance is involved. (If it did, the Q should stay the same when I change the shunt C, but it doesn't, as you pointed out. I also see by calculation that the equivalent L in the series model is reduced by the C, while the R stays the same, so the Q as defined by Terman's series model does go down as a result of shunt C. The ratio of Rp to Lp in a parallel model also drops by the same factor when shunt C is introduced.) I think I've run into a classic trap, of using an approximation and not paying careful enough attention to its limitations and range of validity. It'll take me a while to do the math and see just what's going on.

The presence of shunt C does reduce inductor Q as defined by Terman. The equivalent series R and L of an inductor with stray C are

Ls = L*(1 - (omega^2)*L*C) - (R^2)*C
Rs = R

and Q = omega*Ls/Rs

where
L = inductance
R = resistance in series with L
C = stray C, modeled across the series RL
omega = radian frequency = 2*pi*f

Below self-resonance, Ls is always less than L, so Q is less than it would be if C weren't present. As I mentioned above, you can also construct a parallel RL equivalent and get the same Q. My earlier posting was definitely wrong, as verified by both these calculations and your measurements.

I'll work on the problem of measuring Q as I have been when I have time, and post what I come up with.

Thanks for pointing out the error in my explanation!

Lyle Koehler wrote:

Well, I try to be sure of my facts before I make a posting, but sometimes I'm wrong, as I was here. I'll never have a reputation as always being right, but I hope people understand that I do try to give the right answer. And when I don't, at least I post a correction as quickly as I can. That way at least I'm hopefully doing more good than harm. And when someone spots a wrong answer I've posted, it's a wonderful opportunity for ME to learn something new!

Tom Bruhns wrote:

> it seemed like the true Q and the apparent Q would be different.

Imagine a coil reactance wL with "no" stray capacity Cs, in "parallel" with a resistor R at a
"fixed" frequency w (w = 2 pi f).

Then Q = R/wL.

Now add a "small" and "lossless" capacitance Cs. Cs causes the reactance of the coil and capacitor combination to "increase", therefore the Q' = R/wL' becomes smaller. wL' is the increased value of "effective" inductive reactance.

The stray Cs is an inseparable part of this particular coil and the effective Q' at frequency w
includes the effect of Cs.

An AC circuit analysis of the parallel RLCs circuit leads to the following formula:

Q' = Q (1 - w^2 LCs)

For a fixed w and L, Q' decreases as Cs increases. Cs is assumed to be lossless.

But wait, there is something else! If the coil has a tuning capacitor that "absorbs" the stray
capacitance Cs and tunes the circuit to resonance at w, then the Q' of the coil reverts back to
Q. That is, the true L is tuned by Cs plus the tuning capacitor, so the Q of the tuned circuit
at frequency w is the same as the "true" Q of the coil.

The Boonton Q meter tunes to resonance in this manner. The Boonton correction factor is based
on the fact that some of the capacitor current circulates within the coil itself and does not
flow through the 0.02 ohm measuring resistor, so the Boonton Q reading is low. Also, the inductance reading is the effective inductance at frequency w, not the true inductance.

I have the Model 260-A and the Manual. Figure B, page 20, shows that Q errors and inductance
relative errors are both plotted on the same curves.

Something else: the assumption that Cs is a "lumped" C is not exactly correct, it is more distributed somewhat like a transmission line, and it does affect the Q to a small extent in a
way that is very complicated.

Source record: 75364

I think Tom's definition of Q is a good one, but it'll take me, at least, a bit of head-scratching to decide how to translate this into quantities I can easily measure.

Again, a fundamental problem is that while the Q of an ideal L-R combination is well-defined and easy to measure, a real inductor has this shunt capacitance involved. The Boonton procedure seems kind of ridiculous to me, because determining the distributed capacitance of the inductor would be quite a job in itself, requiring some sort of measurement at at least two frequencies and some ugly algebra. Looking again at the model of a series RL, with C across the combination, the C shouldn't affect the Q of the LR "inductor" combination. The Q of the LR combination itself (which is apparently what the Boonton correction is referring to) will be different than the Q of the three-component model (which may be what it's measuring). Terman's definition would be for the three-component model, where an "effective inductance" (the equation for which was in my last posting) or reactance is compared with the "effective resistance" to find the Q. Even if no energy is lost in the capacitor, its presence does increase the current in the inductor, which would reasonably lead to higher loss.

So the first thing to determine is whether we're measuring the Q of the LR portion only (as the "corrected" Boonton measurement seems to be doing), or the Q of the whole LRC circuit (which seems to be what Terman defines as inductor Q). Then, how to define it. Tom's certainly is fundamental, but how do we translate it to measurable quantities, and how do we use it in practice? Incidentally, it looks like my method of measuring bandwidth and center frequency may be measuring the Q of the LR combination only. But so far I haven't succeeded in deriving it.

I've seen inductor Q used as a parameter in the design of sharp bandpass filters. Here, what I'd do is use Terman's definition and an "equivalent" L and R. Even though the "equivalent" L is influenced by both the R and C, I'd expect the real component to behave pretty much like a series RL of the "equivalent" values over a narrow frequency range (assuming the component is well below self-resonance). In this case, Terman's definition leads to a value which is useful in a real application. Would the more fundamental one based on energy be as useful, especially if we didn't know in advance how much of the apparent inductance is due to shunt C?

>To describe a PEP, a power level in watts, as having an rms value is
>meaningless.

I thought PEP was defined (in the regs) as the r.m.s power (calculated over one cycle) at the peak (crest) of the modulation envelope.

There may be some people who think you can only take the root of the mean square of the voltage or current, but I don't see any reason why you can't have an RMS of any waveform. RMS cash flow? I have a poor rms to peak there.

So why is this meaningless? Only if not qualified.

TO sort of address the original question, how to convert PEP to RMS, well you can't without more data.

Perhaps too few people know the meaning of PEP, the relationship between the peak and average power of various signals, and what this means in practice in
amplifier design. I expect a sample of assistants in Dixons might have a hard
time with the concept.

E.g. a "linear" amplifier driven at 100W r.m.s is what PEP ? Not necessarily 400W, especially if the PSU is drooping, which it probably is doing. It depends on what's going in.

Music power is defined as:

4 times the absolute maximum pulsed rms power with all
distortion products in phase averaged over 1 cycle at whatever
frequency gives the largest number.

Peak Music Power is the music power squared.

I have never liked RF sensed switching for just the reasons (problems) you mentioned. If the rig is capable of switching the amp, I would suggest that you do it that way. Some Icoms have very little switching capability and need a small transistor added to their switching circuits. I don't know if you are using an Icom rig or not but it much easier to add the transistor and run the keying line than it is to get a finicky RF sensed circuit to work!! If you take the relay coil to ground with the PTT line, I'll guaran-damn-tee you it will work!!

Having said that, it does appear that you need a cap to add some "hang" time to the sensing circuit. Good luck.

Regards,

Bill

Be careful with Radio Designer; the statement

IND 2 0 L=22nH Q=30

results in an _ideal_ inductor without any warning
unless you specify a frequency, too.

That gave me a filter that was too good to be true...

I have a Yaesu FT-230R mobil 2-meter rig that has the creeping crud
LCD-itis, and of course, Yaesu no longer stocks the part. I need
either:

1. A dead FT-230R that still has a clear LCD
2. An alternate source for the part (not likely, I know, as these things
tend to be custom). The
number etched into the glass is H1313-0. Maybe the 430R uses the
same display?
3. Information from anyone who has adapted the rig to use 7-segment
LED's.
4. A copy of the schematic of the display circuit, so I can attempt #3
myself.

Thanks in advance for any help that anyone can provide.

The last time I looked, it seemed that freq. counters were selling for less than you could get the parts. However, I do recall that the Jan. & Feb. '75 issues of QST had just what you want. ;-> There were a few more between then and now and The Radio Amateur's Handbook from at least 1981 on usually has some freq. counter project. If you've had trouble finding something on the net, perhaps a trip to the local library is in order. Look in the periodical indexes as well as the electronics section. Don't forget to ask local hams too.

you didn't quote diameter and length of the coil, believe best Q is when
it is the wire diameter is equal to distance between the turns, and
length to diameter of the coil is about 1:1. Q decreases fast when the
coil is shorter but not as fast when it becames longer.

Why is it that iron dust core should only have 330 degrees covered by
winding for optimum Q? (ref.: ARRL HBK96 fig 25.34 pg 25.23)

Source record: 75440

I am looking for an RLB design to cover VHF/UHF. I have bought a directional coupler for 1-10GHz, but still need one for lower frequencies. ARRL HBK96 page 26.39 shows one. I want to modify it to have termination (lower resistance) connected via a BNC connector (Rn). I studied a commercial RLB using bifilar wound transformer, seems to be two thin wires straight through 3 ferrit beads.
Believe I have seen the design described in a handbook, but cannot find it. Is it just to use a pair of thin enamelled copper wires, winded slightly together and thread them through the hole of the 3 ferrit beads? Most ferrite beads are ?=2000, is this too high?

Tom it seems you pointed the right reason for reducing the Q with
capacitance. When you approximate the turns of a coil, not only the inter
turns capacitance increase, there is an increase in the interaction of
adjacent turns. The current must circulate in a smaller cross section
of wire due to "proximity effect", increasing the equivalent series
resistance.
It seems the current will be more dense at the inner and outer coil
surfaces.

RF switching "seems" so simple, yes, but even if you get it working as
well as it possibly can, there will still be problems with the relay
dropping out in mid-speech and producing clicks and pops - not to
mention the stress on relays and semiconductors due to switching
significant levels of RF.

Hard switching using a wire from the PTT contacts on the rig is much
more reliable... and ultimately simpler.

6224. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-30 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <368A4C8D.95A8F09C@mlecmn.net>
Source record: 75443

After making all my convincing arguments about inductor Q, I finally did what I should have done in the first place -- grab a handbook and look up the definition of Q. My old (4th edition) of Reference Data for Radio Engineers describes the method for Q measurement, and it is electrically equivalent to what Roy has been using. The handbook also shows the circuit for the Boonton 160A Q meter, a predecessor of the model I have. To get the "true Q" as defined in terms of bandwidth, it is necessary to correct the readings from the Boonton Q meter. The correction is given by:

Q(true) = Q * (C + Co)/C

where Q is the indication on the Boonton meter, Co is the distributed capacitance of the coil, and C is the capacitance reading of the Q meter. A procedure is described for plotting C versus 1/f^2 to determine the Co of the coil.

I had assumed that the readings on the Q meter were gospel, and that the Q obtained from bandwidth measurements was an approximation. Apparently it's the other way around. Since I'm primarily interested in high-Q inductors as loading coils for electrically short antennas, the Q meter measurements are a good indication of coil "quality" for my application. But they are only an approximation of the actual inductor Q according to the handbook definition.

Model 810 Thermo-Probe lets you heat-test integrated circuit components
with constant ease and accuracy. No
ovens, no heat chambers ... everything is in the open and easily
accessible. Thermo-Probe applies regulated and
accurate heat to integrated circuits, diodes, resistors, capacitors,
transistors or any other type of electronic
component. You pinpoint heat-drift and thermoelectric problems right
on your test bench or production line.
Thermocouple Sensing Probe provides temperature reading from any IC
during heat test .Thermo-Probe Model 810
is ideal for Design Engineers, QPL Managers, Technicians and
Trouble-Shooters. Heat Tips are available for
nearly all types of electronic components at:
http://www.micro-technical.com/ Unit is in working condition but no
additional warranty provided and sold as is.

Check the ebay auction:

I'm not the final authority on this, but as it turns out (no pun intended)
the inductance and Q of a toroidal inductor are not affected significantly
if the windings do not cover the entire core. So by leaving a portion
-- and here, it's only 10% of the core -- without windings, you gain
two significant advantages:

o It is easier to mount the core vertically to a PC board
0 You can clamp the core when you wind it, and not have to re-space
the windings after you take the core out of the clamp or vise

6227. Icom FL44A in a Kenwood TS-850?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-30 00:00:00 UTC
From: Anders Lindekrantz <anders.lindekrantz@telia.com>
Message-ID: <368A604C.B3F55D0D@telia.com>
Source record: 75446
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I recently bought a used Kenwood TS-850. Before I bought it I read all reviews and articles I could lay my hands on. One of the few complaints i noticed was that the 455kHz SSB filter is a "moderate quality ceramic filter". Having an Icom FL44A 455kHz SSB filter on hand, the idea of substituting the stock ceramic filter for the FL44A (which I believe is a pretty good SSB filter) popped up. Before ripping the rig apart I would like to hear your opinion about the idea.

If anybody has done this "operation" I would love to hear about the result. Otherwise, could anyone with more technical insight than myself give his/her opinion on the following questions:

1) Does the FL44A has the same center frequency as the stock Kenwood filter?

2) Is the Icom filter compatible withe the stock Kenwood filter with respect to filter impedance and attenuation?

3) Any other reasons why the swap might not be successful?

Sounds like you need to add an RC in the circuit to
provide a little delay to prevent the relay chatter.
Keep in mind that there is no carrier in the SSB mode
so the sensing circuit will only come on while
you're talking and will drop out when you stop.
It's a must to have a delay circuit for SSB use.
When you first start talking, the RC will charge
and slowly discharge between syllabels (sp?)
and words so that you don't get the annoyance
of the relay dropping out .

The distributed C of an inductor will change its self resonant
frequency. This parameter may be more important than Q depending on the
application. Generally you want to operate the inductor well below its
self resonant frequency. I like network analyzers better than "Q"
meters :)

I thought the main electrical reason for the 330 degree rule was to keep the
two points of maximum RF potential difference (the two ends of the inductor)
apart in order to lower the capacitance and leakage around the inductor.

I have the following test instruments for sale.
All in working order.

Marconi Sig Gen model TF2015/1 complete with TF2171 digital sync unit.
Covers 10MHz to 520MHz AM/FM

£110 for both units.....sorry will not split.

Dymar 1785 Modulation meter AM/FM tuneable from 30MHz to 480MHz. IF and AF outputs. I have 2 of these units at £30 each.

Dymar distortion factor meter type 1765 range 20Hz to 20KHz. £25

Dymar AF wave analyser type 1771. £35.

Marconi TF1065A TX/RX output test set. Measures AF power and RF power etc. £25

Please email me for contact details.

John@flycatcher.freeserve.co.uk

Thanks, John G0JJL

Lyle Koehler (lyle@mlecmn.net) wrote:
: After making all my convincing arguments about inductor Q, I finally did what I should
: have done in the first place -- grab a handbook and look up the definition of Q. My old
: (4th edition) of Reference Data for Radio Engineers describes the method for Q
: measurement, and it is electrically equivalent to what Roy has been using. The handbook
: also shows the circuit for the Boonton 160A Q meter, a predecessor of the model I have.
: To get the "true Q" as defined in terms of bandwidth, it is necessary to correct the
: readings from the Boonton Q meter. The correction is given by:

: Q(true) = Q * (C + Co)/C

: where Q is the indication on the Boonton meter, Co is the distributed capacitance of the
: coil, and C is the capacitance reading of the Q meter. A procedure is described for
: plotting C versus 1/f^2 to determine the Co of the coil.

: I had assumed that the readings on the Q meter were gospel, and that the Q obtained from
: bandwidth measurements was an approximation. Apparently it's the other way around. Since
: I'm primarily interested in high-Q inductors as loading coils for electrically short
: antennas, the Q meter measurements are a good indication of coil "quality" for my
: application. But they are only an approximation of the actual inductor Q according to the
: handbook definition.

Thanks for the followup, Lyle. I was intending to ask you about that, with
respect to accounting correctly for the capacitance shunt across the coil,
because it seemed like the true Q and the apparent Q would be different.
In fact, my reason for posting this is to try to get us back to a very
basic definition of Q which should be applicable to any single resonance,
be it lumped LC, distributed line, cavity resonator, pendulum, air mass
in a bottle, ...

Q = energy stored/energy lost per radian

Note that this really only works for a resonator, and that when we talk
about Q of an inductor, we're extrapolating: we're saying that IF the
inductor is used in a resonator at the specifice frequency, the inductor
itself (not counting the losses in the capacitor which is also part of
the resonator) will loose a certain amount of energy per radian.

With that definition, we _should_ be able to relate the effects of
parasitic capacitance to Q...to energy loss. If the capacitance itself
is not lossy, we have to look for ways that that capacitance has done
something like increase the effective resistance of the wire in the
inductor, or caused some other loss somewhere else. For me, this is
one of those "I'll know what I'm looking for when I see it," but I'm
not good enough at fields to see the answer clearly yet. Perhaps Kevin
will join us.

(Is it important that the capacitance is mainly between adjacent turns and NOT really like an external capacitor shunt across the inductor? What if anything is the significance of trying to wind air-core solenoid coils with wire spaced about a 2-wire-diameter pitch for use at HF and above, but generally using close-wound coils at MF and below?)

(It's really disappointing to me that Grover's book on inductance calcs seems to completely ignore the issue of losses or Q!)

RF sensing is only useful as a second guarantee(*) that linear amplifier
is switching. It is so easy connecting a 10k resistor from a switched
12v to the transceiver antenna connector and another 100k from antenna
connector of linear amplifier to drive a logic circuit, could be the
same circuit as the RF sensing circuit.

Source record: 75457

I'm currently building a more-or-less single chip counter based on the Harris ICM7216D chip. The data sheet has lots of detail and example circuits. The chip drives 7 segment LED displays. I downloaded the PDF data file from Harris.

The chip itself is good to 10 Mhz, but if you use a 2.5 Mhz crystal instead of 10 Mhz and prescale with a couple of flip-flops, you can go to 40 MHz.

It has a built in oscillator, but I'm having trouble trimming my crystal to the right frequency with their circuit, so I'm looking at an external timebase oscillator now.

I got the chip from D.C. Electronics, I think. I got the displays from B.G. Micro (common cathode 7 segment LEDs)

BTW, I'm building this circuit to replace the one I built from the circuit described in QST back in the 70's, which got old and erratic due to my sloppy construction techniques. (I hope I'm better now.)

Thank you, your doing both of us a favor. You get to keep your amp forever and I get to laugh at you every time you spam the newsgroups. Your about as comical as this asshole I laughed at the hamfest that carried an Icom 551 around for 3 years. he was scratching his ass wondering why people were giving him dirty looks when he responded he wanted $700 for the thing. He was off in la la land pulling his pud in bewilderment why he couldn't sell the radio. He finally decided to keep it, which was great since nobody lost out. I finally thanked him for not budging on his price since I picked one up for $125 in immaculate condition. So I will extend the same gratitude to you since you are doing me a big favor. I hope you sell your amp for your asking price. Best of luck doing so, you lost a valued customer by being hard headed.

6243. Re: Question about high Q inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-30 00:00:00 UTC
From: Lyle Koehler <lyle@mlecmn.net>
Message-ID: <368AE6FA.265D7EE@mlecmn.net>
Source record: 75462

I think the effect on losses is the same whether the total effective shunt capacitance is placed across the coil terminals or is treated as multiple capacitors between adjacent turns,
but I won't attempt to prove it. Also, the increase in coil losses when windings are spaced less than two wire diameters apart may be due more to the current distribution in the wires than to the distributed capacitance. As far as I know, the two-wire-diameter rule continues to
apply to coils for MF and LF when they are made from solid wire. However, at low frequencies
the losses can be reduced by using Litz wire, made of many strands of small wire that are insulated from each other. With Litz wire, turns spacing can be reduced below two wire diameters without seriously degrading the Q. Many LowFERs (including me) use basket-wound Litz-wire loading coils in order to minimize the effects of closely spaced windings.

I don't have a good reference on inductance calculations, not even a copy of Terman. Brian Beezley's program COIL.EXE (which was included in the software that came bundled with the ARRL
Handbook for several years) will calculate inductance, Q and distributed capacitance of single-layer solenoids made from a number of different metals on a variety of coil form materials. It's a handy tool for predicting the performance of various coil configurations.

Message-ID: <368b3dfb.5522010@news.unibw-muenchen.de>
Source record: 75373

Another code for this tube is 7836.

Allow me go give you the short typical data here.

Vf = 26.5 V, If = .85 A, oxide coated cathode, indirectly heated.
Base is 5 pin Giant.

Va = 750 V, Vg2 = 250 V, Ia = 100 mA, S = 9 mS.

At 30 MHz:
Class C CW Wout = 200 W @ Va = 750 V
Class C fone (anode modulation) Wout = 130 W @ Va = 600 V
Class B SSB Wo = 220 W @ Va = 750 V

Class B modulator Wo = 300 W @ Va = 750 V

Source record: 75377

According to Terman's _Radio Engineering_ (p. 31, Third Ed.):

"The total effect that the numerous small coil capacitances have can
be represented to a high degree of accuracy by assuming that they can
be replaced by a single condenser of appropriate size shunted across
the coil terminals."

The absolute best source I've ever found on coil calculations is the
Radiotron Designer's Handbook, edited by F. Langford-Smith. Grab
hold of a copy of this if you ever get the chance. (Or, if you don't
want it, let me know!)

Anyone have build a CW Keyer with Basic Stamp ?

72/73 de Phil.

6255. FS: Dynaco/ Heath/ Scott/ Fisher

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-31 00:00:00 UTC
From: Ross Lipman <rl1856@ix.netcom.com>
Message-ID: <368B8880.6A97@ix.netcom.com>
Source record: 75379

12/31

Hello All,

I have the following that I would like to sell:

Dynaco PAS-3 / Heath W-5 pr / Scott LT-110 / Fisher 400

Dynaco PAS-3 Preamp.

Original stock condition. Looks and sounds great without any hum !
Unit takes 4 x 12ax7 tubes, which are nice and strong. Unit is full
function with aux, tuner, spare, tape, tape head, phono and special
inputs (- the last 3 have RIAA eq). Also with loudness and filter
switches. With metal case, copy of manual and my personal
notes file (how to bypass the tone controls and other switches for
example). Some smudgeing of lettering around power switch.

$160.00 + shipping
--

HH Scott LT-110 stereo tube tuner/ FM only.

This was originally a kit. In very clean original condition and
includes the rare metal case. Overall, this one is in excellent
condition and sounds very nice. Nice stereo reception and adjacent
channel rejection. Only a few very minor scratches on the face plate
and some small smudgeing of lettering around one of the knobs.

$130.00 + shipping
--

Heath W-5 pair.

These are "for rebuild" not plug and play.

Both are small transformer- 16309 and gold chassis- no cages or tubes.
One is complete but untested.
Other is in 3 pieces- output, power transformer and chassis/ choke- with
all other parts. Both chassis are clean.

$325.00 + shipping for all. Otherwise I will part out as follows:

2 x 16309 output transformers $75.00 each
2 x Power transformers $75.00 each
2 x Chokes $25.00 each
2 x Chassis $25.00 each
--

Parting out a Fisher 400 receiver (this one is not worth restoring):

one (1) output transformer # T-1020-116-6 $30.00
one (1) power transformer # T-1020-124 $30.00
one (1) MPX-65 multiplex unit $40.00
-(this is the same unit used in the 500/800 series receivers
and FM-50-90-100-200 tuners)

pots: Balance, Selector, Bass, Treble $25.00 for all 4
Face plate- clean lettering, few scratches $20.00
Chassis with can caps, rf coils and sockets $30.00

--> or will sell chassis with pots and face plate for $40.00 <--

No tubes, slide switches, on-off volume switch or knobs.

>and I get to laugh at you every time you spam the newsgroups.

You should take off your blinkers. $600 is only £360. Now that is a little expensive, but not excessively so over here. Perhaps you forget the world is not just the USA.

For your information. A commercial 6m amplifier here using a 3-500z runs to around £800 - thats $1300.

>You should take off your blinkers. $600 is only £360. Now that is a little
>expensive, but not excessively so over here. Perhaps you forget the world
>is not just the USA.
>

I didn't forget the world is just the USA. With that being said, I'm sure his price isn't that unreasonable if you decide on the price of the additional shipping to get it from the USA to the UK, or just a few states over, and the high asking price to begin with?

I'm just factoring all the risk of buying a home built amp with a tube of unknown quality and questionable building techniques (Since it would be bought sight unseen without any warranty or any other like it to base it's quality by.) I'm not saying it's poorly built, but, it's a big unknown.

>For your information. A commercial 6m amplifier here using a 3-500z runs
>to around £800 - thats $1300.
>

This doesn't sound unreasonable to me. Plus you have a baseline to judge quality and price by. You also have a baseline for what the price should be for any given condition.

Like anything else, you have to put things in perspective, it's really worth what someone is "willing" to pay for it.

It doesn't bother me that he doesn't want to negotiate a fair price for both parties concerned, he already stated, "He wouldn't sell it to me at any price", which is fine by me. What I find totally pointless is spamming the newsgroups with an add that he has demonstrated that he has no intentions of selling the merchandise in the first place.

I guess his logic is spamm the hell out of us and someone will buy his amp at an overinflated price to stop him from posting constantly. As I said, I wish him the best of luck selling it.

I have done this -- a month or so back. I've only seen 1 piece
of traffic out of that list since then! (And, I think *that*
msg may have been some clueless person's "unsubscribe" message. :-)
Is this an *active* list?
Or, is my "subscribe" simply screwed up somehow.

I'm building a "Voice Robot" to use those 6 sec./10 sec. digital voice
recorders that are showing up REAL CHEAP in the surplus catalogs.
I have a PIC-less, Rube Goldberg prototype working now.
Next I need to control it all with a PIC -- to do the timing,
to handle Rcv/Xmitt, and kick off the recorder playback.
As part of my timing design, I am going to include a
"first-and-third"/"second-and-fourth" mode for meteor scatter
work.

6 secs doesn't sound like much, but I can do:

"HELLO CQ W3DHJ Delta Mike 68" <-- for 6m/2m 'dead band' use.
"CQ CONTEST W3DHJ Delta Mike 68" <-- for 6m/2m contest use.
"HELLO CQ Whiskey 3 Delta Hotel Juliet" <-- for 15m/10m 'dead band' use.

(-: I suppose it could be tougher for a 3x4 call. :-)

Anyway -- is ham-pic' active?

6267. Re: PEP vs RMS

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-12-31 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <368BC7EB.566DD73A@teleport.com>
Source record: 75391

Although it's possible, as you say, to calculate an RMS value for
power (as you can for any waveform), I don't know what practical
meaning or use it would have.

RMS voltage and current are useful quantities. The RMS voltage or
current is the value of DC which would cause the same power
dissipation in the resistive part of the circuit as the actual varying
voltage or current.

The AVERAGE, not RMS, power is the value of constant (DC) power which
would cause the same amount of dissipation in the resistive part of
the circuit as the actual varying power. The RMS power, which for most
waveforms is different than the average power, has no similar
equivalence. I've never seen RMS power calculated for any purpose.

Just such an article appeared in Oct. Ham Radio 1985. It was for extending the range of the Yaesu FRG9600 V/U receiver down to 0-60 MHz using a 100 MHz L.O. I built one using a custom PCB and installed it inside the 9600- still performs wonderfully. Far Circuits has the article and a PCB for under $10 as I recall.

Hi Ed, This type of feed thru capacitor, a Hi Voltage one in this case is available, Its something you rarely see anywhere like flea markets and so on......but I know that Surplus sales of Nebraska has them in their catalog, but they are BIG $$$$$!! I would try it without using it in your amp, you might get away with it, you will know if you need it. If you can find one cheap, by all means use it, but I have been looking for this type of thing all the time, and I never seem them. You might get by without it. But right now, Surplus Sales is the only one I know who has them.you might roust someone here that will sell you one if they have one to sell.Good Luck...73 LOU

Source record: 75394

Sorry old man, but you thought wrong.

Take a look at the "term and limitations ..... " booklet covering UK licensing conditions.

The definition of PEP makes no reference to RMS values.

It does mention average power over one RF cycle but even that is belt and braces. One cycle is depicted as a sinewaveform of volts and amps. The term Root - Mean - Square merely desribes the arithmetical process of converting instantaneous values of volts or amps into watts for a given load resistance.

RMS and Peak values are applicable only to such things as Volts and Amps and are important because, in general, for a given waveform they (plus average values) are 3 different things and measuring instruments are designed to respond to only one of those values at a time.

PEP is the power output during that tiny instant of the modulation envelope when it is at its peak. It is measured in watts of which there is only one sort. It is the same power as when the modulation envelope is held at its peak value by the simple process of holding down the CW key. There is then sufficient time to measure it.

Thanks, Bill, for your followup posting...

William E. Sabin (sabinw@mwci.net) wrote:

: Tom Bruhns wrote:

: > it seemed like the true Q and the apparent Q would be different.

: Imagine a coil reactance wL with "no" stray capacity Cs, in "parallel" with a resistor R at a
: "fixed" frequency w (w = 2 pi f).

: Then Q = R/wL.

: Now add a "small" and "lossless" capacitance Cs. Cs causes the reactance of the coil and
: capacitor combination to "increase", therefore the Q' = R/wL' becomes smaller. wL' is the
: increased value of "effective" inductive reactance.

: The stray Cs is an inseparable part of this particular coil and the effective Q' at frequency w
: includes the effect of Cs.

OK, what if instead of modeling the coil loss as a shunt resistance, we
model it as a series resistance, and say that

Q = wL/Rs

Now if something causes the reactance of the coil+stray capacitance to
increase, the Q apparently increases...

: An AC circuit analysis of the parallel RLCs circuit leads to the following formula:

: Q' = Q (1 - w^2 LCs)

: For a fixed w and L, Q' decreases as Cs increases. Cs is assumed to be lossless.

: But wait, there is something else! If the coil has a tuning capacitor that "absorbs" the stray
: capacitance Cs and tunes the circuit to resonance at w, then the Q' of the coil reverts back to
: Q. That is, the true L is tuned by Cs plus the tuning capacitor, so the Q of the tuned circuit
: at frequency w is the same as the "true" Q of the coil.

Yes, to get the true (coil) Q, I think we must know just how much
energy is lost in the coil (and its parasitics).

: The Boonton Q meter tunes to resonance in this manner. The Boonton correction factor is based

: on the fact that some of the capacitor current circulates within the coil itself and does not
: flow through the 0.02 ohm measuring resistor, so the Boonton Q reading is low. Also, the
: inductance reading is the effective inductance at frequency w, not the true inductance.

: I have the Model 260-A and the Manual. Figure B, page 20, shows that Q errors and inductance
: relative errors are both plotted on the same curves.

: Something else: the assumption that Cs is a "lumped" C is not exactly correct, it is more
: distributed somewhat like a transmission line, and it does affect the Q to a small extent in a
: way that is very complicated.

: Bill W0IYH

Roy Lewallen (w7el@teleport.com) wrote:
: I think Tom's definition of Q is a good one, but it'll take me, at
: least, a bit of head-scratching to decide how to translate this into
: quantities I can easily measure.

:-) Yes, things often come down to that problem. Actually it may
not be all that difficult: if you excite a resonator with a
transient and watch the natural response, that will tell you
just where the pole-pair is, and that in turn will tell you the Q.
I don't think it's too much mental gymnastics to go from the
natural response to energy lost per unit time. In fact, the
measurement of bandwidth gives you the same thing, _assuming_
that there is only one pole-pair. Perhaps questioning that
assumption may be just what will yield some better answers
about how the parasitic capacitance lowers Q. With distributed
capacitance, there are additional series and parallel self-
resonances as you go above that first self-resonance you get
by just assuming the stray is a single shunt capacitance.
It's pretty clear to me that if the stray can be modeled as
simply a single shunt across the whole coil, there's no
direct effect on Q.

I'm not claiming to have answers, just trying to stir some
more thoughts into the pot. Wish I had more time to think
seriously about this problem, but I can't do that right now.
(Though I'll be watching this thread and tossing out more
as it occurs to me, or if I find interesting writing on the
subject.)

g0mjw.freeserve.co.uk wrote in message <76fvhl$f9k$1@news4.svr.pol.co.uk>...
... snip...
|I thought PEP was defined (in the regs) as the r.m.s power (calculated over
|one cycle) at the peak (crest) of the modulation envelope.
|
... snip ...

actually, FCC part 97.3(b)(6) defines PEP as:
"The average power supplied to the antenna transmission line by a
transmitter during one RF cycle at the crest of the modulation envelope
taken under normal operating conditions."

Thus, while the average power out of the transmitter is a function of the
r.m.s. value of the modulation envelope, the PEP value is effectively the
power output at the *instant* of maximum output for the waveform being used
for modulation. You can get an "average" PEP by adding a number of
"instances" and then dividing by that number.

I hope that this clears up the confusion.

What you say is correct if "modulation envelope" is taken to mean the voltage or current waveform describing the envelope, but not if you mean the RMS value of envelope power. RMS and average power are different values for most waveforms, and as I pointed out in an earlier posting, the RMS power has no useful meaning, at least not for this application (or any other I know of).

Message-ID: <368C536C.978777BC@teleport.com>
Source record: 75402
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.cad,sci.electronics.design

Artech House's _Microwave Engineers' Handbook_, Vol. 2, shows "Epoxy, polyester, or silicone fiberglass laminate (120 lbs/cubic foot)" to have a dissipation factor of about 0.007 at "microwave frequencies", defined as 1 - 30 GHz (with a caution that values will vary with frequency). The value is sure to vary a lot with formulation as well as frequency.

Reference Data for Radio Engineers gives about 0.02 - 0.03 for epoxy resin at 3 GHz.

I recently designed a 6 GHz oscillator on the stuff with no problem, but the design would be quite tolerant of loss, and I made no effort to determine just how much there was.
